Abstract

This paper proposes a novel transmission channel of US monetary policy through the FX swap market: the *synthetic dollar funding channel*. First, I show empirically that a contractionary US monetary policy shock widens deviations from covered interest rate parity (CIP) in the post-global financial crisis period. Then, I construct a two-country New Keynesian model with financially-constrained banks and an FX swap market. In the FX swap market, US banks are suppliers of synthetic dollar funding and obtain CIP deviations as intermediation fees arising from the limit to arbitrage while non-US banks are demanders for matching currencies for holding US capital. In equilibrium, CIP deviations are endogenously determined so that the FX swap market clears. From the calibrated model, a contractionary US monetary policy shock widens CIP deviations because it tightens the leverage constraint of US bank. This implies that the gap between cost of synthetic dollar funding and direct dollar funding becomes larger. Then, spillover to non-US and spillback to US output, investment, and inflation are amplified compared to the counterfactual case in which CIP holds. Finally, I show that central bank swap lines can attenuate the synthetic dollar funding channel.

^{*}I am greatly indebted to my advisors, Stephanie Schmitt-Grohé, Martín Uribe, and Jesse Schreger, for their guidance and support in my dissertation. I would also like to thank Hassan Afrouzi, Fernando Cirelli, Richard Clarida, Wenxin Du, Matthieu Gomez, Émilien Gouin-Bonenfant, Jennifer La'O, Frederic Mishkin, Christian Moser, Tommaso Porzio, and seminar participants at Columbia University, 23rd Macro-Finance Society Workshop, Asia Meeting of the Econometric Society in East & Southeast Asia, Federal Reserve Board Dissertation Fellowship Seminar, 19th WashU Economics Graduate Student Conference, 2024 Annual Carey Finance Conference for helpful comments.

[†]Department of Economics, Columbia University, jl5491@columbia.edu

1 Introduction

In the aftermath of the global financial crisis (GFC), significant and persistent violations of covered interest rate parity (CIP) have emerged, largely due to strengthened regulations on riskless arbitrage (Du, Tepper, and Verdelhan, 2018). CIP deviations refer to the differences between the costs of direct dollar funding and synthetic dollar funding via foreign exchange (FX) swap markets, implying the emergence of the gap between these two costs since the GFC.¹ Many non-US banks, smaller banks and even global banks facing financial distress, lack access to direct dollar funding markets and therefore rely on this synthetic dollar funding and face synthetic dollar funding cost (Ivashina, Scharfstein, and Stein, 2015; Rime, Schrimpf, and Syrstad, 2022); the share of synthetic dollar funding to the total dollar funding has been 15-20% for the past 5 years (Khetan, 2024). However, previous literature on the transmission of US monetary policy has primarily focused on direct dollar funding markets (see Bräuning and Ivashina (2020), for example).

This paper proposes a novel transmission channel of US monetary policy through FX swap markets, referred to as the synthetic dollar funding channel. The key mechanism of the synthetic dollar funding channel lies in the effect of US monetary policy on CIP deviations and its role in amplifying the global transmission of US monetary policy shocks. Financial intermediaries, whose balance sheets are affected by US monetary policy, price these CIP deviations. As CIP deviations are wedges in dollar funding markets, they work as a financial accelerator because the synthetic dollar funding cost reacts more strongly than the direct dollar funding cost. In this sense, this paper extends the credit channel literature, starting with Bernanke and Gertler (1995), with CIP deviations playing a similar role as the external finance premium or credit spread in that literature.²

First, I present empirical evidence on the effects of US monetary policy on CIP deviations. Using high-frequency data, I estimate that a contractionary US monetary policy shock widens CIP deviations significantly in the post-GFC (2008-) period. For instance, 3-month CIP deviations widen by 35 basis points (bp) in response to a 1 percentage point (pp) contractionary shock, which is substantial considering that the post-GFC average of CIP deviations for G10 currencies is around 21bp. These results are shown to be robust to different constructions of changes in CIP deviations, the information effect of monetary policy, and the Fed response to news channel.

Given the above empirical findings, I construct a two-country New Keynesian model with

¹Synthetic dollar funding is dollar funding through FX swap markets by converting local currency funding into US dollar using FX swap contracts. Let us denote the US interest rate and local currency interest rate as R and R^* , the spot exchange rate and forward exchange rate expressed in local currency per US dollar as S and F respectively. Then, synthetic dollar funding cost is given by R^*S/F . Following the convention of measuring cross-currency bases, this paper defines CIP deviations as direct dollar funding costs minus synthetic dollar funding costs, *i.e.* $R - R^*S/F$.

²When internal financing is unavailable or insufficient, borrowers need to rely on external financing. However, external financing is more expensive than internal financing due to the moral hazard problem, with the wedge as the external financing premium. A monetary contraction raises the external finance premium through balance sheets of borrowers or lenders, and this comovement amplifies the transmission channel of monetary policy.

financially-constrained banks to shed light on the synthetic dollar funding channel. The novel part of this model is embedding an FX swap market into a standard general equilibrium model. US and non-US banks constitute the FX swap market, and CIP deviations are endogenously determined as the equilibrium price in the FX swap market.

According to the model, the supply of synthetic dollar funding by US banks is increasing in the size of CIP deviations. As CIP deviations are negative, as ensured by the model's calibration, the arbitrage strategy involves borrowing in US dollar and lending in non-US currency. In this model, US banks are arbitrageurs of CIP deviations because, by assumption, only they can borrow US dollar directly. Arbitraging negative CIP deviations is equivalent to supplying synthetic dollar funding, as US banks sell US dollar and buy non-US currency in the spot market.

However, there is a key financial friction: US banks face a limit on arbitrage due to stricter regulations on riskless arbitrage in the post-GFC period. Then, CIP deviations reflect the shadow cost of balance sheet space of US banks, which is tied to the tightness of the CIP arbitrage constraint. In order to supply larger amounts of synthetic dollar funding, US banks require more balance sheet space for arbitrage. This tightens the limit on arbitrage, raising the shadow cost of balance sheet space. Consequently, CIP deviations need to be larger, resulting in an upward-sloping supply schedule of synthetic dollar funding.

The model also predicts that non-US banks' demand for synthetic dollar funding is decreasing in the size of CIP deviations. Non-US banks hold non-US capital with returns denominated in non-US currency as well as US capital with returns in US dollar. For simplicity, I assume that direct dollar funding is not available to non-US banks. Then, their liabilities are denominated entirely in non-US currency, creating a currency mismatch between their US capital holdings and liabilities. Non-US banks can resolve this mismatch by funding US dollar synthetically, with CIP deviations as intermediation fees for currency matching. The optimal amount of synthetic dollar funding is chosen from the trade-off between regulatory benefits of currency matching and CIP deviations. As CIP deviations become more negative, currency matching becomes more expensive, and thus the demand for synthetic dollar funding falls.

Then, the model is calibrated to match long-run first moments of the US and the rest of the world economies. Based on the calibrated model, impulse responses to a 1pp contractionary US monetary policy shock are derived. The results show that CIP deviations widen by approximately 30bp, driven by the tighter leverage constraint on US banks. This occurs because the US monetary contraction reduces the net worth of US banks due to a decline in the price of capital they hold. As a result, the constraint on CIP arbitrage tightens, increasing the shadow cost of balance sheet space. This means that US banks require larger CIP deviations to use balance sheet space for arbitrage. Notably, this model produces an impact response of CIP deviations that is quantitatively similar to the empirical estimate.

In order to explore the amplification of spillovers and spillbacks, the baseline impulse responses are compared with the counterfactual responses where there is no limit on CIP arbitrage and, thus, CIP always holds. First, synthetic dollar funding decreases more than in the counterfactual scenario due to a reduction in the supply of synthetic dollar funding by US banks. The higher shadow cost of balance sheet space reduces the supply of synthetic dollar funding. Next, declines in both US and non-US aggregate variables, such as capital stock and output, are amplified by approximately 15-20%. This amplification occurs due to the widening of CIP deviations. Intuitively, larger CIP deviations mean that synthetic dollar funding costs increase more than direct dollar funding costs. As a result, spillovers are amplified because the larger CIP deviations—higher intermediation fees—reduce the net worth of non-US banks, triggering financial accelerator effects. On the other hand, spillbacks are amplified as non-US banks demand less amount of US capital. Since non-US banks seek currency matching for holding US capital, the reduction in synthetic dollar funding and larger CIP deviations lower their demand for US capital holdings.

Finally, I investigate effects of central bank swap lines on the synthetic dollar funding channel. The swap line policy is known to impose an upper bound on CIP deviations, stabilizing dollar funding markets during financial distress periods (Bahaj and Reis, 2022). Then, the swap line policy can prevent the widening of CIP deviations following US monetary contraction and mitigate the amplification effects. In order to explore the effect on the synthetic dollar funding channel, the swap line policy is modeled as an occasionally binding upper bound on CIP deviations. Then, I compare impulse responses with and without the swap line policy. In response to the same shock as the baseline model, the widening of CIP deviations becomes smaller due to the ceiling imposed by the swap line policy. As a result, the decline in synthetic dollar funding is dampened, leading to higher US capital holdings by non-US banks and attenuating the transmission to capital, output, investment, and inflation.

Related Literature

After the onset of the GFC, there has been extensive literature on CIP violations (see Baba, Packer, and Nagano (2008), Du, Tepper, and Verdelhan (2018), for example). This paper is related to research exploring the relationship between variations in CIP deviations and macroeconomic and financial variables. Du, Tepper, and Verdelhan (2018) and Cerutti, Obstfeld, and Zhou (2021) regress CIP deviations on interest rate differentials and suggest the role of monetary policy, although they do not estimate causal effects. Jiang, Krishnamurthy, and Lustig (2021) estimate the causal effect of high-frequency identified US monetary policy shocks on the Treasury basis. This paper uses the LIBOR basis instead since it gauges frictions in interbank dollar funding markets, which are the main focus of this paper, while the Treasury basis is more related to convenience yields.

[Keerati \(2020\)](#) and [Viswanath-Natraj \(2020\)](#) take a similar approach as in this paper for the empirical estimation part. They use high-frequency identified monetary policy shocks and LIBOR bases as the measure for CIP deviations. In both papers, US monetary policy is estimated to have insignificant effects on CIP deviations in the post-GFC period. This contrasts to the results in this paper due to the difference in sample periods, estimation methods, and series of monetary policy shocks. This paper also shows robustness of the results to using various choices of dependent and explanatory variables.

Regarding the theoretical explanation for CIP deviations, this paper narrows the gap between the macro and finance literature by modeling CIP deviations in a standard business cycle framework. First, macroeconomic research has focused on the failure of uncovered interest rate parity (UIP) and its implication for the macroeconomy. [Kollmann \(2005\)](#) introduces exogenous shocks to UIP deviations into a two-country model and shows that UIP shocks are main sources of exchange rate fluctuations. In [Gabaix and Maggiori \(2015\)](#), UIP deviations are generated endogenously by segmented international financial markets and financially-constrained global financiers. [Itskhoki and Mukhin \(2021\)](#) incorporates this framework into the conventional business cycle model and explain several puzzles in international macroeconomics. [Kalemli-Özcan \(2019\)](#), [Giovanni et al. \(2022\)](#), and [Varela and Kalemli-Özcan \(2022\)](#) relate UIP deviations to global risk appetite or global financial cycle and discuss spillover effects through UIP deviations. [Schmitt-Grohé and Uribe \(2022\)](#) distinguish transitory and permanent US monetary policy shocks and analyze the effect of each shock on UIP deviations based on a small open New Keynesian model with portfolio adjustment costs.

The closest works to my paper in terms of methodology are [Akinci, Şebnem Kalemli-Özcan, and Queralto \(2022\)](#) and [Devereux, Engel, and Wu \(2023\)](#). They derive UIP deviations from a two-country model with financial intermediaries à la [Gertler and Kiyotaki \(2010\)](#); [Akinci, Şebnem Kalemli-Özcan, and Queralto \(2022\)](#) investigate the effect of uncertainty shock while [Devereux, Engel, and Wu \(2023\)](#) focus on the effect of first-order shocks in the presence of collateral advantage of US government bonds. However, all the above papers work on UIP deviations rather than CIP deviations. Even though UIP deviations are usually higher than CIP deviations, CIP deviations are crucial for banks since they are usually required to hedge currency risks. Said differently, CIP deviations are pivotal barometers for gauging the cost of dollar funding. This paper contributes to the literature on interest rate parity and its implication for global economies by shedding light on CIP deviations and the synthetic dollar funding channel.

On the other hand, finance literature on CIP deviations has been based on partial equilibrium models with static or finite horizon. In [Ivashina, Scharfstein, and Stein \(2015\)](#), CIP deviations emerge due to the margin requirement for the arbitrage. [Iida, Kimura, and Sudo \(2018\)](#) extend this paper by microfounding the investment decisions of arbitrageurs and show that interest rate differentials are important for determining CIP deviations. [Liao and Zhang \(2020\)](#) model the demand for currency

hedging based on mean-variance utility, showing the importance of net foreign asset positions. This paper extends this literature to an infinite horizon and general equilibrium model and investigate the transmission channel of monetary policy to global economies.

The work by [Bacchetta, Davis, and van Wincoop \(2024\)](#) is closely related to this paper as they study the joint determination of CIP deviations and the exchange rate. They shed light on new FX-swap-related shocks affecting the exchange rate as well as the amplification of the effects of conventional shocks through FX swap markets. On the other hand, this paper focuses only on monetary shocks and instead show that the transmission to various macroeconomic aggregates, not only to the exchange rate, is amplified based on the less-stylized business cycle model.

This paper is also related to recent papers on convenience yields. In [Jiang, Krishnamurthy, and Lustig \(2024\)](#) and [Kekre and Lenel \(2024\)](#), convenience yields are determined from the demand for safety that USD provides: exogenously given demand function for US government bonds ([Jiang, Krishnamurthy, and Lustig, 2024](#)) or money-in-the-utility function ([Kekre and Lenel, 2024](#)). [Bianchi, Bigio, and Engel \(2022\)](#) argue that settlement risks in interbank markets create the precautionary demand for US dollar and CIP deviations appear as dollar liquidity premium. Unlike these papers, I explain CIP deviations from the limit to arbitrage and demand for currency matching, unrelated to the safety or the liquidity that US dollar provides.

With some earlier papers ([Baba and Packer \(2009a,b\)](#)), the effects of central bank swap lines on CIP deviations and asset prices have been recently studied, including [Bahaj and Reis \(2022\)](#) and [Kekre and Lenel \(2024\)](#). However, these papers look at high-frequency changes, which is often impossible for macroeconomic aggregates. This paper supplements the literature by analyzing the effect of the swap line policy on the transmission channel of US monetary policy based on a quantitative model.

This paper is organized as follows. In section [2](#), I present empirical evidence on effects of US monetary policy on CIP deviations. Section [3](#) presents a two-country New Keynesian model with banks and the FX swap market. In section [4](#), I calibrate the model and present impulse responses to contractionary US monetary policy shock. In Section [5](#), effects of central bank swap lines on the synthetic dollar funding channel are discussed. Section [6](#) concludes.

2 Empirical Evidence

In this section, I estimate effects of US monetary policy on CIP deviations in order to provide empirical evidence on the transmission of US monetary policy to synthetic dollar funding costs. For this purpose, I construct panel dataset consisting of CIP deviations of G10 currencies and high-frequency identified US monetary policy shocks from January 2008 to April 2021. Then, effects of US monetary policy on CIP deviations in the post-GFC period are estimated by OLS regression

with currency fixed effects. It is shown that a contractionary US monetary policy shock widens 3-month CIP deviations significantly.

2.1 Empirical Strategy

Effects of US monetary policy on CIP deviations are estimated by the following OLS regression with currency fixed effects:

$$\Delta cid_{j,h,t} = \alpha_j + \beta_h \Delta mp_t + \epsilon_{j,h,t} \quad (2.1)$$

The dependent variable $\Delta cid_{j,h,t}$ is the one-day change in CIP deviations between currency j and USD with maturity h . In the right-hand side, the explanatory variable Δmp_t is the change in US monetary indicator while α_j is the currency fixed effect and $\epsilon_{j,h,t}$ is the disturbance term. Then, β_h measures effects of US monetary policy on CIP deviations for each maturity h . The sample consists of G10 currencies with maturities spanning from 3-month to 10-year.^{3,4} Maturities longer than or equal to 3-month are chosen since they are more related to business cycle frequency, and also not affected by quarter-end effects (see [Du, Tepper, and Verdelhan, 2018](#)). The sample period starts from January 2008 and ends at April 2021, which is the post-GFC period with non-zero CIP deviations. This regression is conducted at the frequency of the FOMC announcement.⁵

In order to identify β_h , Δmp_t needs to be an exogenous monetary policy “shock”. Since CIP deviations are market prices of synthetic dollar funding in FX swap markets, they are general equilibrium objects. This means that CIP deviations depend not only on monetary policy stance but also on other macroeconomic variables that affect supply or demand of synthetic dollar funding. Since those macroeconomic variables are also correlated with US monetary policy, (2.1) is susceptible to the endogeneity problem.

This paper identifies Δmp_t following an extensive literature on high-frequency identification of monetary policy shocks (see [Gürkaynak, Sack, and Swanson, 2005](#); [Nakamura and Steinsson, 2018](#), for example). As those papers, one or multiple principal components from changes in interest rate futures over a narrow window around each FOMC announcement are regarded as US monetary policy shocks. The key identifying assumption is that all the information on fundamentals are reflected to monetary policy just before the FOMC announcement. This assumption is satisfied since we take the window narrow enough that monetary policy cannot respond to the changes in fundamentals over that window. Hence, surprises in the interest rate futures are only due to unsystematic part of

³G10 currencies include Australian dollar (AUD), Canadian dollar (CAD), Swiss franc (CHF), Danish krone (DKK), euro (EUR), British pound (GBP), Japanese yen (JPY), Norwegian krone (NOK), New Zealand dollar (NZD), and Swedish krona (SEK).

⁴Maturities in this sample are 3-month, 1-year, 2-year, 3-year, 5-year, 7-year, and 10-year.

⁵There are 8 regularly scheduled FOMC meetings in a year. The sample in this empirical analysis does not include unscheduled meetings.

monetary policy. Details for this identification will be covered in Section 2.2.

2.2 Measurement and Data

2.2.1 CIP Deviations

CIP deviations of G10 currencies are measured as

$$cid_{j,h,t} \equiv r_{\$,h,t} - (r_{j,h,t} - \rho_{j,h,t})$$

where $r_{\$,h,t}$ and $r_{j,h,t}$ are risk-free rates of the USD and currency j respectively that mature h periods after time t . $\rho_{j,h,t}$ is the forward premium of currency j against the USD with maturity h , defined as the difference between the log of forward and spot exchange rates. Spot and forward exchange rates are expressed in units of currency j per USD, so the increase in the exchange rate means the appreciation of the US dollar.

For 3-month maturity, cross-currency bases are calculated by the above equation. First, the interbank offered rate (IBOR) is used as the proxy for the risk-free rate.⁶ Daily data of IBORs for each currency can be obtained from Bloomberg.⁷ Next, $\rho_{j,h,t}$ is measured as the mid price of bid and ask for the forward premium using London closing rates, and is adjusted by the actual trading days.

For maturities longer than or equal to 1-year, the forward premium is inaccurate because forward exchange markets are illiquid. Instead, following [Du, Tepper, and Verdelhan \(2018\)](#), CIP deviations are directly measured as cross-currency bases from cross-currency swaps traded in over-the-counter (OTC) markets. Similar to the forward premium above, the mid price of bid and ask for the cross-currency bases is used.⁸ Daily data for cross-currency bases are available at Bloomberg, and Jesse Schreger kindly shared the data with me.

Figure 1 shows 3-month CIP deviations of G10 currencies against the USD. As [Baba, Packer, and Nagano \(2008\)](#) report, there have been substantial deviations from CIP since the GFC while CIP deviations had been negligible before the GFC. Note that CIP deviations can take both positive or negative values. For example, CIP deviations of Australian Dollar (AUD) and New Zealand Dollar (NZD) are positive on average while those of other currencies are negative on average.⁹ In Table 1

⁶IBORs have been replaced by the Secured Overnight Financing Rate (SOFR) since December 31 2021. Because the sample period ends at April 2021, the replacement of the IBORs does not matter in this paper.

⁷For USD, GBP, JPY, and CHF, we use LIBOR as the benchmark rate. EURIBOR is used for the case of EUR. For other currencies, their own benchmark rates are used. See [Du, Im, and Schreger \(2018\)](#) for details.

⁸We can back out the forward premium by replicating the fixed-for-fixed currency swap. First, an investor pays the fixed-for-floating interest rate swap $r_{j,h,t}^{irs}$ in order to exchange fixed payments into floating payments. Then, she pays cross-currency basis to exchange the floating payments in currency j into those in the USD since the cross-currency swap exchanges floating interest payments. Finally, floating payments in the USD is exchanged into fixed payments by paying the USD interest rate swap $r_{\$,h,t}^{irs}$. Since this investment strategy replicates the fixed-for-fixed currency swap with the return rate of the forward premium, $\rho_{j,h,t} = r_{j,h,t}^{irs} + cid_{j,h,t} - r_{\$,h,t}^{irs}$.

⁹[Liao and Zhang \(2020\)](#) show that CIP deviations are negative (positive) when net foreign asset position of a country is positive (negative). This is because arbitrageurs take the opposite position of the counterparty countries

which presents simple averages of summary statistics of CIP deviations across all G10 currencies in the pre-GFC (2000-2007) and the post-GFC (2008-) period, we can see that mean and median of CIP deviations are negative for every maturity in the post-GFC period. This means that CIP deviations are negative on average in the post-GFC period despite heterogeneity across currencies.

Figure 1: 3-month CIP Deviations of G10 Currencies against the USD

Note. This figure shows 10-day moving average of 3-month CIP deviations for G10 currencies against the USD from 1/1/2000 to 4/30/2021.

After calculating CIP deviations, I take an one-day change in CIP deviations $\Delta cid_{j,h,t} \equiv cid_{j,h,t} - cid_{j,h,t-1}$ as the dependent variable of the regression (2.1). If t corresponds to the date of the FOMC meeting, then $\Delta cid_{j,h,t}$ measures the change in CIP deviations from one day before the FOMC meeting to the day of the FOMC meeting. Even though there are time-zone differences between various currencies, currency markets and cross-currency swap markets are primarily OTC markets with 24-hour trading. Hence, the one-day change in CIP deviations is used as the baseline dependent variable in this empirical analysis. In Appendix B.1, I show that the results do not change much even if I use the two-day change in CIP deviations as the dependent variable.

However, there is a caveat to the interpretation of $\Delta cid_{j,h,t}$ because CIP deviations can take both positive or negative values. The change in CIP deviations has completely different meaning

whose hedging demand comes from their net foreign asset position denominated in US dollar. If a country has positive net foreign asset position, then arbitrageurs should take negative position of US dollar, implying that CIP deviations should be negative for positive arbitrage profits. In light of this argument, CIP deviations of AUD and NZD are positive since these countries have negative net foreign asset positions.

Table 1: Summary Statistics of CIP Deviations

	3M		1Y		2Y		3Y	
	Pre-GFC	Post-GFC	Pre-GFC	Post-GFC	Pre-GFC	Post-GFC	Pre-GFC	Post-GFC
Mean	-2.48	-20.93	0.25	-17.82	0.49	-16.31	0.60	-15.11
Median	-2.40	-17.87	0.18	-15.94	0.56	-15.01	0.74	-13.97
S.D.	5.42	20.99	2.11	14.29	1.99	12.79	2.10	12.43
Autocorr.	0.52	0.75	0.72	0.78	0.72	0.79	0.72	0.79
	5Y		7Y		10Y			
	Pre-GFC	Post-GFC	Pre-GFC	Post-GFC	Pre-GFC	Post-GFC		
Mean	0.76	-13.29	0.58	-12.02	0.34	-10.13		
Median	1.06	-12.08	1.03	-10.70	0.75	-8.70		
S.D.	2.51	12.63	2.79	12.89	3.12	13.14		
Autocorr.	0.72	0.79	0.72	0.79	0.73	0.79		

Note. This table presents summary statistics of CIP deviations for each maturity of 3-month, 1-year, 2-year, 3-year, 5-year, 7-year, and 10-year. For each maturity, each statistic of CIP deviations is a simple average of the statistics across G10 currencies. The pre-GFC period is from 1/1/2000 to 12/31/2007 while the post-GFC period is from 1/1/2008 to 4/30/2021.

depending on the sign of CIP deviations. For example, when CIP deviations are negative, then the decline in CIP deviations means that CIP deviations widen from zero. On the contrary, if CIP deviations are positive, then the decline in CIP deviations means the narrowing in this case. Since CIP deviations are negative on average as shown in Table 1, we can consider the decline in CIP deviations as the widening of CIP deviations. If I instead take the absolute value of CIP deviations, then an increase in this value always indicates a widening of the CIP deviations. Appendix B.2 shows that using the absolute value of CIP deviations as the dependent variable does not change the results.

2.2.2 US Monetary Policy Shocks

In order to identify US monetary policy shocks, five interest rate futures are used: federal funds futures immediately following the FOMC announcement (FF1), federal funds futures immediately following the next FOMC announcement (FF4), and 3-month Eurodollar futures at horizons of two, three, four quarters ahead (ED2, ED3, and ED4 respectively). Note that interest rate futures other than FF1 contain information on forward guidance which has become a crucial policy tool since the GFC and the following zero lower bound periods. Then, surprises in these interest rate futures are measured over 30-minute window around each FOMC announcement: changes from 10 minutes before to 20 minutes after the FOMC announcement.

Following Nakamura and Steinsson (2018), one principal component is extracted from surprises in five interest rate futures. This factor is denoted as *NS* in this paper, and it contains information on not only overnight federal funds rate target but also forward guidance. Alternatively, we can extract two orthogonal principal components, target factor (*Target*) and path factor (*Path*), following Gürkaynak, Sack, and Swanson (2005). *Target* indicates the shock only on federal funds target while *Path* can be interpreted as the forward guidance shock. All three series of monetary policy shocks

are normalized such that a 1pp increase in the shock raises the 1-year US treasury rate by 1pp. Thus, we can treat the one unit of shock as a 1pp or 1pp contractionary shock on US monetary policy. Series of monetary policy shocks used in this paper come from [Acosta \(2023\)](#).

2.3 Estimation Results

Table 2 displays β_{3M} of the regression (2.1) for the maturity h of 3-month. Regression results for other maturities are shown in Appendix A.1, with discussion about the term structure in Appendix A.2. Column (1) is the estimation result when NS is used as the US monetary policy shock whereas column (2) is the result when *Target* and *Path* are used as proxies for the shock. In order to consider the cross-sectional dependence across G10 currencies, Driscoll-Kraay standard errors are reported in the parentheses.

β_{3M} measures the basis point change in 3-month CIP deviations in response to a 1pp contractionary US monetary policy shock. Since CIP deviations are the gap between the synthetic dollar funding costs and the direct dollar funding costs, $-\beta_{3M}$ can be interpreted as an additional cost (in bp) to pay for the synthetic dollar funding in response to the 1pp US monetary policy shock.¹⁰ For example, if β_{3M} is estimated as -35, then the synthetic dollar funding rises by 35bp more than the direct dollar funding cost.¹¹

In response to 1pp contractionary NS shock, 3-month CIP deviations are estimated to decline by 35bp. This estimate is significant not only statistically but also economically; 3-month synthetic dollar funding cost increases 35bp more than direct dollar funding cost does when the US policy rate rises by 1pp. This implies profound amplification of the effect of US monetary policy on the dollar funding cost through FX swap markets. When we decompose NS into target and path factors, we can see that most of the effect comes from the federal funds target rather than the forward guidance; *Target* (*Path*) declines 3-month CIP deviations by 28bp (7bp).

Since $cid_{j,h,t} \equiv r_{\$,h,t} - (r_{j,h,t} - \rho_{j,h,t})$, β_h can be decomposed into effects on $r_{\$,h,t}$, $-r_{j,h,t}$, and $\rho_{j,h,t}$. In Table A.5 of Appendix A.3, we can see that effects on synthetic dollar funding costs mostly come from effects on forward premium. Note that this decomposition is just an accounting exercise, and does not provide a causal explanation that effects on CIP deviations come from FX swap market frictions.¹²

In Appendix B, I show that the baseline results are robust to different choices of the dependent variable such as two-day changes in CIP deviations, changes in absolute values of CIP deviations,

¹⁰In Section 2.2, we have seen that the average CIP deviations are negative, implying that negative β_h corresponds to the widening of CIP deviations.

¹¹Direct dollar funding cost, for example LIBOR, does not move 1-1 with 1-year US treasury rate as it will be shown in Appendix A.3. For this reason, we cannot interpret β_{3M} as an additional *percentage* increase in the synthetic dollar funding cost.

¹²According to [Du, Tepper, and Verdelhan \(2018\)](#), CIP deviations have emerged due to FX swap market frictions such as limit on arbitrage since the GFC.

Table 2: Effects of US Monetary Policy Shock on 3-Month CIP deviations

	(1)		(2)
<i>NS</i>	-35.34*** (13.40)	<i>Target</i>	-28.33*** (6.386)
		<i>Path</i>	-7.006* (3.626)
Currency FE	Y		Y
R^2	0.135		0.203
Observations	1047		1047

Note. This table presents the regression results of 3-month CIP deviations on 1pp contractionary US monetary policy shock. Column (1) is the estimation result when *NS* is used as the US monetary policy shock whereas column (2) is the result when *Target* and *Path* are used as proxies for the US monetary policy shock. Units of the estimates are in basis points. Driscoll-Kraay standard errors are reported in the parentheses. N denotes the number of observations of the regression respectively. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

and different choices of the explanatory variable such as information-robust monetary policy shocks (Miranda-Agrippino and Ricco, 2021), and monetary policy shocks robust to Fed response to news channel (Bauer and Swanson, 2023a).

3 The Model

I construct a two-country (the US and non-US) production economy with nominal price rigidity and financial intermediaries subject to leverage constraints. The novel contribution of this model is embedding a FX swap market into a standard business cycle model. As a CIP deviation is the price of synthetic dollar funding in the FX swap market, it is determined as a general equilibrium object from the supply and the demand for synthetic dollar funding.

3.1 Structure of FX Swap Market

Before moving on to the theoretical analysis, I first start with describing the basic and simplified structure of FX swap markets and FX swap contracts. In this model, US banks and non-US banks are main players in the FX swap market. Suppliers of synthetic dollar funding in FX swap markets are large global banks who can borrow US dollar directly from households or MMFs in the US. They sell the US dollar and buy and invest the foreign currencies in spot exchange markets while taking the opposite position in forward markets to hedge currency risks. In doing so, global banks arbitrage CIP deviations, and at the same time supply synthetic dollar funding by selling US dollar in spot markets.¹³ These top-tier global banks are usually US banks, so US banks are suppliers in FX swap

¹³Arbitrage is usually mediated by broker-dealers in practice, but this paper does not distinguish them from global banks because most broker-dealers are part of global banks in the form of subsidiaries. In other words, balance sheets of broker-dealers and global banks are consolidated in this paper.

markets.¹⁴

On the other hand, banks, non-bank financial institutions (such as insurance companies, pension funds, hedge funds), and non-financial firms of non-US countries demand synthetic dollar funding in FX swap markets. In order to simplify the analysis, this paper focuses on the banking sector in non-US countries as the demand-side of FX swap markets. Since non-US banks usually lack access to direct dollar funding, there is a currency mismatch problem when they hold USD-denominated assets. As banks are heavily penalized on currency mismatches, they fund US dollar synthetically by buying dollar spot and selling dollar forward in FX swap markets. In this way, non-US banks are demanders of synthetic dollar funding as counterparties of US banks in FX swap markets. [Kloks, Mattille, and Ranaldo \(2024\)](#) support this setting using data from Continuous Linked Settlement (CLS), the largest multi-currency cash settlement system.¹⁵

Figure 2 summarizes cash flows of a FX swap contract between a US and non-US bank. For notational convenience, the currency of the US is denoted as USD (\$) while the non-US currency is denoted as EUR (€). The FX swap contract consists of two legs: spot leg and forward leg. Today, both parties of the FX swap exchange their own currencies at the spot exchange rate S expressed in units of EUR per USD. The US bank exchanges $\$X$ into $\text{€}S \cdot X$, so it obtains $\text{€}S \cdot X$ while the non-US bank obtains $\$X$. At the same time, they enter into a forward contract at the forward exchange rate F . This forward leg locks in the exchange rate of tomorrow by the forward exchange rate predetermined today. The notional value of the FX swap is assumed to be $\$R^*(S/F)X$ where R^* is a non-US risk-free rate. This means that US bank hedges all of its risk-free return on $\text{€}S \cdot X$. Indeed, US bank gets $\$R^*(S/F)X$ while paying back $\text{€}R^*S \cdot X$ to the non-US bank, which are the proceeds from investing $\text{€}S \cdot X$ into non-US risk-free assets.

Figure 2: Structure of a FX Swap Contract

¹⁴Arbitraging CIP deviations by borrowing in US dollar and lending in foreign currency implicitly assumes that CIP deviations defined as cross-currency bases are negative. As we can see from Table 1, CIP deviations for G10 currencies are negative on average since 2008.

¹⁵Non-US global banks borrow dollar synthetically from US global banks, but they are net suppliers of synthetic dollar funding due to their supply to non-US smaller banks and other financial intermediaries. Since US banks are counterparties in this paper, it is without loss of generality to assume that non-US banks are demanders for synthetic dollar funding.

3.2 US Economy

3.2.1 Household

The life-time utility function of the representative US household is

$$E_0 \sum_{t=0}^{\infty} \beta^t \left[\frac{C_t^{1-\gamma} - 1}{1-\gamma} - \kappa \frac{L_t^{1+\varphi}}{1+\varphi} \right]$$

where C_t is the aggregate consumption and L_t is the aggregate labor supply. $1/\gamma$ is the the elasticity of intertemporal substitution, $1/\varphi$ is the Frisch elasticity, and κ is the parameter for disutility of labor supply.

The household buys C_t at the price of P_t and deposits D_t to financial intermediaries at gross deposit rate R_t . On the other hand, the household obtains labor income $W_t L_t$ from supplying labor to domestic firms, net profits Π_t from all firms and financial intermediaries, and net lump-sum transfer TR_t from the US government. Then, the sequential budget constraint of the household is given by

$$P_t C_t + D_t = W_t L_t + R_{t-1} D_{t-1} + \Pi_t + TR_t \quad (3.1)$$

The first-order conditions of the household's utility maximization problem with respect to C_t , L_t , and D_t give rise to

$$\kappa C_t^\gamma L_t^\varphi = \frac{W_t}{P_t} \quad (3.2)$$

$$E_t [\Lambda_{t,t+1}] R_t = 1 \quad (3.3)$$

for the stochastic discount factor (SDF) of the representative household

$$\Lambda_{t,t+1} = \beta \left(\frac{C_{t+1}}{C_t} \right)^{-\gamma} \left(\frac{P_t}{P_{t+1}} \right) \quad (3.4)$$

(3.2) is the intratemporal condition between consumption and labor supply while (3.3) is the standard Euler equation for the deposits.

3.2.2 Capital Good Producers

There are perfectly competitive capital good producers who purchase aggregate investment goods at P_t , installing them, and sell to banks at Q_t . The law of motion for the aggregate capital stock is then

$$K_t = I_t + (1 - \delta) K_{t-1} \quad (3.5)$$

When installing investment goods, there is an investment adjustment cost $\frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1 \right)^2$ per unit of investment good. Then, the per-period profit function of capital good producers is given by

$$\Pi_t^K \equiv Q_t I_t - P_t I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1 \right)^2 \right)$$

Consequently, the following life-time profit maximization problem

$$\max_{\{I_{t+s}\}_{s=0}^{\infty}} E_t \left[\sum_{s=0}^{\infty} \Lambda_{t,t+s} \Pi_{t+s}^K \right]$$

yields the first-order condition for I_t as

$$Q_t = P_t \left[1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1 \right)^2 + \psi_I \frac{I_t}{I_{t-1}} \left(\frac{I_t}{I_{t-1}} - 1 \right) \right] - E_t \left[\Lambda_{t,t+1} P_{t+1} \psi_I \left(\frac{I_{t+1}}{I_t} \right)^2 \left(\frac{I_{t+1}}{I_t} - 1 \right) \right] \quad (3.6)$$

3.2.3 Retailers

C_t is aggregated by perfectly competitive consumption good retailers who assemble composite consumption of domestically-produced US goods $C_{H,t}$ and composite consumption of non-US goods $C_{F,t}$. The aggregation technology is given by the following constant elasticity of substitution (CES) function:

$$C_t \equiv \left[\omega^{\frac{1}{\nu}} C_{H,t}^{\frac{\nu-1}{\nu}} + (1-\omega)^{\frac{1}{\nu}} C_{F,t}^{\frac{\nu-1}{\nu}} \right]^{\frac{\nu}{\nu-1}}$$

where ω is the home-bias parameter and ν is the elasticity of substitution between domestic and imported consumption.

From the profit maximization problem, we can obtain the demand functions for $C_{H,t}$ and $C_{F,t}$ as

$$C_{H,t} = \omega \left(\frac{P_{H,t}}{P_t} \right)^{-\nu} C_t \quad (3.7)$$

$$C_{F,t} = (1-\omega) \left(\frac{P_{F,t}}{P_t} \right)^{-\nu} C_t \quad (3.8)$$

for the aggregate consumer price index (CPI) as

$$P_t = \left[\omega P_{H,t}^{1-\nu} + (1-\omega) P_{F,t}^{1-\nu} \right]^{\frac{1}{1-\nu}}$$

where $P_{H,t}$ is the price of domestic goods and $P_{F,t}$ is the price of imported goods.

Let us define the terms-of-trade T_t faced by the US as $P_{F,t}/P_{H,t}$. From the above equation for

P_t , $P_{H,t}$ and $P_{F,t}$ can be expressed as functions of the terms-of-trade as

$$P_{H,t} = P_t [\omega + (1 - \omega)T_t^{1-\nu}]^{-\frac{1}{1-\nu}} \quad (3.9)$$

$$P_{F,t} = P_t [\omega T_t^{-(1-\nu)} + 1 - \omega]^{-\frac{1}{1-\nu}} \quad (3.10)$$

Similar to the aggregate consumption, perfectly competitive investment goods retailers assemble domestically-produced investment good $I_{H,t}$ and imported investment good $I_{F,t}$ into the aggregate investment I_t as

$$I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1\right)^2\right) \equiv \left[\omega^{\frac{1}{\nu}} I_{H,t}^{\frac{\nu-1}{\nu}} + (1 - \omega)^{\frac{1}{\nu}} I_{F,t}^{\frac{\nu-1}{\nu}}\right]^{\frac{\nu}{\nu-1}}$$

Note that the aggregated product contains not only the aggregate investment I_t but also the investment adjustment cost because it is paid by capital producers. Then, the demand functions for investment goods are¹⁶

$$I_{H,t} = \omega \left(\frac{P_{H,t}}{P_t}\right)^{-\nu} I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1\right)^2\right) \quad (3.11)$$

$$I_{F,t} = (1 - \omega) \left(\frac{P_{F,t}}{P_t}\right)^{-\nu} I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1\right)^2\right) \quad (3.12)$$

3.2.4 Wholesalers

As we will see in Section 3.2.5, there is a continuum of firms in $[0, 1]$ producing each variety. Perfectly competitive wholesalers aggregate these varieties into a single good and sell to retailers. There are two sets of wholesalers: domestic and export wholesalers. Domestic wholesalers assemble $Y_{H,t}(j)$ into domestically-spent output $Y_{H,t}$ while export wholesalers assemble $Y_{H,t}^*(j)$ into exported output $Y_{H,t}^*$. The aggregation technologies are given by

$$Y_{H,t} \equiv \left[\int_0^1 Y_{H,t}(j)^{\frac{\epsilon-1}{\epsilon}} dj\right]^{\frac{\epsilon}{\epsilon-1}}$$

$$Y_{H,t}^* \equiv \left[\int_0^1 Y_{H,t}^*(j)^{\frac{\epsilon-1}{\epsilon}} dj\right]^{\frac{\epsilon}{\epsilon-1}}$$

where ϵ is the elasticity of substitution between varieties.

These wholesalers purchase $Y_{H,t}(j)$ and $Y_{H,t}^*(j)$ from firms at the price of $P_{H,t}(j)$ and $P_{H,t}^*(j)$,

¹⁶The aggregate price of investment goods is the same as the CPI because the aggregate consumption goods and the aggregate investment goods have the same aggregator.

and sell to retailers at $P_{H,t}$ and $P_{H,t}^*$ respectively. Then, the demand functions are

$$Y_{H,t}(j) = \left(\frac{P_{H,t}(j)}{P_{H,t}} \right)^{-\epsilon} Y_{H,t} \quad (3.13)$$

$$Y_{H,t}^*(j) = \left(\frac{P_{H,t}^*(j)}{P_{H,t}^*} \right)^{-\epsilon} Y_{H,t}^* \quad (3.14)$$

with the price indices of domestic and exported goods

$$P_{H,t} = \left[\int_0^1 P_{H,t}(j)^{1-\epsilon} dj \right]^{\frac{1}{1-\epsilon}}$$

$$P_{H,t}^* = \left[\int_0^1 P_{H,t}^*(j)^{1-\epsilon} dj \right]^{\frac{1}{1-\epsilon}}$$

Note that the law of one price does not generally hold due to the assumption of local currency pricing (LCP) described in the next section.¹⁷

3.2.5 Firm

A monopolistically competitive firm $j \in [0, 1]$ produces each variety from the production function:¹⁸

$$Y_t(j) = K_{t-1}(j)^\alpha L_t(j)^{1-\alpha}$$

Since this paper focuses on monetary policy shocks, total factor productivity is assumed to be constant at the value of one.

Each firm j minimizes its total cost $W_t L_t(j) + \tilde{R}_{K,t} K_{t-1}(j)$ taking the nominal wage W_t , the nominal rental rate of capital $\tilde{R}_{K,t}$, and its output $Y_t(j)$ as given. The first-order conditions from the cost minimization problem are then

$$W_t = (1 - \alpha) MC_t \frac{Y_t(j)}{L_t(j)} \quad (3.15)$$

$$\tilde{R}_{K,t} = \alpha MC_t \frac{Y_t(j)}{K_{t-1}(j)} \quad (3.16)$$

for the nominal marginal cost MC_t

$$MC_t = \frac{1}{Z_t} \frac{W_t^{1-\alpha} \tilde{R}_{K,t}^\alpha}{(1 - \alpha)^{1-\alpha} \alpha^\alpha} \quad (3.17)$$

¹⁷In Appendix H, I investigate alternative currency pricing paradigms such as producer currency pricing (PCP) and dominant currency pricing (DCP), and show that the results of the model do not change qualitatively. Quantitative differences come from the exchange rate pass-through to the import price.

¹⁸I will use the firm and the variety interchangeably in this paper since each firm produces only one variety.

Note that the marginal cost is common across firms.

Now, I discuss the pricing decision of firm j . We assume LCP, *i.e.*, prices of domestically-sold goods and exported goods are denominated and sticky in the currency of the destination market. Hence, domestically-sold goods are sticky in USD while exported goods are sticky in EUR. Price rigidity is modelled à la [Rotemberg \(1982\)](#) such that there is a price adjustment cost proportional to the nominal aggregate sales. Finally, there is subsidy s on sales to get rid of the pricing distortion from the monopolistic competition in the steady-state. Then, firm j 's periodic profit $\Pi_t^P(j)$ expressed in USD is

$$\begin{aligned} \Pi_t^P(j) = & (1+s) \left(P_{H,t}(j) Y_{H,t}(j) + \frac{1}{S_t} P_{H,t}^*(j) Y_{H,t}^*(j) \right) - TC_t(j) \\ & - \frac{\psi_P}{2} \left[\left(\frac{P_{H,t}(j)}{P_{H,t-1}(j)} - 1 \right)^2 P_{H,t} Y_{H,t} + \left(\frac{P_{H,t}^*(j)}{P_{H,t-1}^*(j)} - 1 \right)^2 \frac{1}{S_t} P_{H,t}^* Y_{H,t}^* \right] \end{aligned}$$

where ψ_P is the parameter for price adjustment cost. The spot exchange rate S_t is expressed in units of EUR per USD, so a rise in S_t means the appreciation of the USD. Then, firm j 's life-time profit maximization problem from period t defined as

$$\max_{\{P_{H,t+s}(j), P_{H,t+s}^*(j)\}_{s=0}^{\infty}} E_t \sum_{s=0}^{\infty} \Lambda_{t,t+s} \Pi_{t+s}^P(j)$$

yields the following first-order conditions as

$$\begin{aligned} (1+s)(\epsilon-1) = & \epsilon \frac{MC_t}{P_{H,t}} - \psi_P \left(\frac{P_{H,t}}{P_{H,t-1}} - 1 \right) \frac{P_{H,t}}{P_{H,t-1}} \\ & + E_t \left[\Lambda_{t,t+1} \psi_P \left(\frac{P_{H,t+1}}{P_{H,t}} - 1 \right) \left(\frac{P_{H,t+1}}{P_{H,t}} \right)^2 \frac{Y_{H,t+1}}{Y_{H,t}} \right] \end{aligned} \quad (3.18)$$

$$\begin{aligned} (1+s)(\epsilon-1) = & \epsilon \frac{S_t MC_t}{P_{H,t}^*} - \psi_P \left(\frac{P_{H,t}^*}{P_{H,t-1}^*} - 1 \right) \frac{P_{H,t}^*}{P_{H,t-1}^*} \\ & + E_t \left[\Lambda_{t,t+1} \psi_P \left(\frac{P_{H,t+1}^*}{P_{H,t}^*} - 1 \right) \left(\frac{P_{H,t+1}^*}{P_{H,t}^*} \right)^2 \frac{S_t}{S_{t+1}} \frac{Y_{H,t+1}^*}{Y_{H,t}^*} \right] \end{aligned} \quad (3.19)$$

Note that $P_{H,t}(j) = P_{H,t}$ and $P_{H,t}^*(j) = P_{H,t}^*$ for all $j \in [0, 1]$ in Rotemberg model.

3.2.6 Financial Intermediary

The financial intermediary side is modeled à la [Gertler and Kiyotaki \(2010\)](#). There is a continuum of perfectly competitive financial intermediaries (“banks” for short) with measure one. US banks can

source their funds from their retained net worth as well as deposits from US households.¹⁹ From this funding, they can purchase US capital or arbitrage CIP deviations by lending to non-US banks in the cash market.²⁰ The detailed intermediation process is explained below.

Figure 3 displays the timeline of the bank decision problem. At the *beginning* of each period t , the state of time t which includes all shocks as well as stay/exit status of banks is unfolded. Banks exit with probability $1 - \sigma$ while they stay as bankers with probability σ .²¹ Exiting banks pay out all of their net worth to households as dividends while they are filled with new banks with initial net worth as transfers of ξ fraction of banks' total asset value from the household.

Figure 3: Timeline of Bank i 's Decision

After observing the state and conditional on staying in the market, bank i retains its net worth $N_{i,t}$ and issues deposits $D_{i,t}$ with gross interest rate R_t .²² The asset side of bank i consists of US capital $K_{H,i,t}$ at the price of Q_t and CIP arbitrage $X_{i,t}$.²³ In the FX swap market, bank i exchanges $\$X_{i,t}$ for $\text{€}S_t X_{i,t}$ and lends it to non-US banks in the cash market at non-US interest rate of R_t^* with the exchange rate risk hedged by the swap contract. The balance sheet identity of bank i expressed in terms of USD is then given by

$$Q_t K_{H,i,t} + X_{i,t} = D_{i,t} + N_{i,t}$$

Note that exchanging $\$X_{i,t}$ for $\text{€}S_t X_{i,t}$ does not appear in period t -balance sheet, meaning that FX swap contracts are off-balance-sheet terms.

From holding $K_{H,i,t}$ from t to $t + 1$, bank i earns rental rate of $\tilde{R}_{K,t+1}$ while the capital is depreciated at the rate of δ . The gross return rate on holding capital can be defined as $R_{K,t+1} \equiv (\tilde{R}_{K,t+1} + (1 - \delta)Q_{t+1})/Q_t$. On the other hand, the gross return rate on $X_{i,t}$ is $R_t^* S_t / F_t$. Since

¹⁹There is an implicit assumption that banks cannot issue deposits in foreign currencies. This shuts down direct funding in foreign currencies, simplifying the analysis.

²⁰In reality, banks can also arbitrage CIP deviations by taking long and short positions in Treasuries. This “real money investor”-like behavior is excluded in this paper since I focus on the interbank flow of funds and LIBOR-bases rather than Treasury-bases.

²¹Without this assumption, banks would retain all of their earnings to the future in order to escape from the leverage constraint. In this case, financial intermediaries are just a veil.

²²In this model, there is no difference between wholesale funding and retail funding. Thus, R_t can be understood as either the deposit rate or the interbank lending rate such as LIBOR, SOFR, or federal funds rate.

²³We exclude the possibility of purchasing non-US capital assets for simplicity.

$\text{€}S_t X_{i,t}$ is lent to non-US banks at period t , $\text{€}R_t^* S_t X_{i,t}$ accrues to the US bank at $t + 1$. As currency risks are hedged at the forward exchange rate F_t , predetermined at period t , US bank exchanges $\text{€}R_t^* S_t X_{i,t}$ for the ultimate return $\$R_t^* (S_t/F_t) X_{i,t}$. With these gross returns from assets and newly issued deposits $D_{i,t+1}$, bank i can purchase US capital $K_{H,i,t+1}$ and engage in CIP arbitrage $X_{i,t+1}$ while repaying deposits $R_t D_{i,t}$. To sum up, we can describe bank i 's budget constraint at $t + 1$ as

$$Q_{t+1} K_{H,i,t+1} + X_{i,t+1} + R_t D_{i,t} = R_{K,t+1} Q_t K_{H,i,t} + R_t^* \frac{S_t}{F_t} X_{i,t} + D_{i,t+1}$$

The above discussion on the balance sheet and the flow of funds of US bank i is described in Figure 4. In particular, the red box presents the cash flows from the FX swap contract.

Balance Sheet		Flow of Funds	
Asset	Liability	t	$t + 1$
$Q_t K_{H,i,t}$	$D_{i,t}$	$-\$Q_t K_{H,i,t}$	$+\$R_{K,t+1} Q_t K_{H,i,t}$
$X_{i,t}$	$N_{i,t}$	$-\$X_{i,t}$	$+\$R_t^* (S_t/F_t) X_{i,t}$
		$+\text{€}S_t X_{i,t}$	$-\text{€}R_t^* S_t X_{i,t}$
		$-\text{€}S_t X_{i,t}$	$+\text{€}R_t^* S_t X_{i,t}$
		$+\$D_{i,t}$	$-\$R_t D_{i,t}$

Figure 4: Balance Sheet and Flow of Funds: US Bank

Combining the balance sheet identity and the budget constraint, we can obtain the law of motion for bank i 's net worth as

$$N_{i,t+1} = \left[(R_{K,t+1} - R_t) \phi_{H,i,t} + \underbrace{\left(R_t^* \frac{S_t}{F_t} - R_t \right)}_{\textcircled{A}} \phi_{X,i,t} + R_t \right] N_{i,t} \quad (3.20)$$

where $\phi_{H,i,t}$ and $\phi_{X,i,t}$ are defined as

$$\phi_{H,i,t} = \frac{Q_t K_{H,i,t}}{N_{i,t}}$$

$$\phi_{X,i,t} = \frac{X_{i,t}}{N_{i,t}}$$

In (3.20), $R_{K,t+1} - R_t$ is the excess return on US capital holdings while $\textcircled{A}$ is the excess return on the CIP arbitrage. Indeed, $\textcircled{A}$ is the negative of CIP deviations, *i.e.* $-cid_t$ where cid_t is defined as^{24,25}

$$cid_t \equiv R_t - R_t^* \frac{S_t}{F_t}$$

²⁴CIP deviations are defined following the tradition of measuring cross-currency bases.

²⁵In this model, cid_t is negative in the steady-state. Hence, $-cid_t$ can be considered as positive near the steady-state.

Hence, US banks earn arbitrage profits of $-cid_t$ as CIP arbitrageurs. At the same time, $-cid_t$ can be interpreted as intermediation fees that US banks obtain from supplying USD through the FX swap market, *i.e.* synthetic dollar funding since they sell US dollar in the spot market. In other words, CIP arbitrageurs are suppliers of synthetic dollar funding.

Let $V_{i,t}$ be continuing bank i 's objective function at the *end* of the period t after the bank made decisions for $K_{H,i,t}$, $X_{i,t}$, and $D_{i,t}$. Then, $V_{i,t}$ is defined as

$$V_{i,t} \equiv E_t \sum_{s=1}^{\infty} (1-\sigma)\sigma^{s-1} \Lambda_{t,t+s} N_{i,t+s} = E_t [\Lambda_{t,t+1} \{(1-\sigma)N_{i,t+1} + \sigma V_{i,t+1}\}]$$

for the US household's SDF $\Lambda_{t,t+s} = \beta^s (C_{t+s}/C_t)^{-\gamma} (P_t/P_{t+s})$. Note that $V_{i,t}$ is the function of $K_{H,i,t}$, $X_{i,t}$, and $D_{i,t}$.

Each bank is subject to a leverage constraint

$$V_{i,t} \geq \left[\left(\theta_{H1} + \theta_{H2} \frac{Q_t K_{H,t}}{P_t} \right) Q_t K_{H,i,t} + \left(\theta_{X1} + \theta_{X2} \frac{X_t}{P_t} \right) X_{i,t} \right] \quad (3.21)$$

where θ_{H1} , θ_{H2} , θ_{X1} , θ_{X2} are parameters for the tightness of the constraint. This constraint is usually motivated from the limited commitment; banks can divert certain fraction of their asset at the end of each period and thus franchise value of banks should be larger than the diverted asset to induce self-enforcement (see [Gertler and Kiyotaki, 2010](#)). However, it can also be interpreted as a leverage constraint imposed by a financial regulatory authority since $V_{i,t}$ is later shown to be linear in net worth. Then, θ 's are parameters for the degree of regulation on leverage.

Importantly, the leverage constraint is imposed not only on capital but also on CIP arbitrage $X_{i,t}$. This is in line with the change in regulatory framework after the GFC; the calculation of leverage ratio changed from risk-weighted basis to non-risk-weighted basis. Arbitrage contains little risk, so the size of arbitrage was not subject to regulation based on risk-weighted leverage ratio. On the other hand, the regulation on non-risk-weighted leverage ratio puts limit on arbitrage activity. This regulatory reform can be parameterized by non-zero θ_{X1} and θ_{X2} while they have been zero before the GFC. Following [Devereux, Engel, and Wu \(2023\)](#), quadratic parameters θ_{H2} and θ_{X2} are introduced to induce stationarity, which is similar to external stationary device in [Schmitt-Grohé and Uribe \(2003\)](#). This can be interpreted as state-dependent regulation that becomes tightened when banks hold larger amount of assets.²⁶ Note that the quadratic parts depend on aggregate assets rather than asset holdings by each individual bank, making quadratic parts exogenous to bank i .

²⁶ θ_{H2} and θ_{X2} are calibrated as small numbers so that they do not affect dynamics of this model significantly. In Appendix I, I conduct sensitivity analysis on values of quadratic parameters and show that impulse responses do not change significantly.

Then, continuing bank i 's optimization problem at the *beginning* of period t is

$$V_{i,t} = \max_{K_{H,i,t}, X_{i,t}, D_{i,t}} E_t [\Lambda_{t,t+1} \{(1 - \sigma)N_{i,t+1} + \sigma V_{i,t+1}\}]$$

subject to the law of motion of net worth (3.20) and the leverage constraint (3.21). In Appendix C, I show that the value function is linear in net worth such that $V_{i,t} = \nu_t N_{i,t}$ by guess and verify method. Let us define the expected discounted returns on each asset class and net worth as

$$\nu_{H,t} \equiv E_t [\Omega_{t,t+1} (R_{K,t+1} - R_t)] \quad (3.22)$$

$$\nu_{X,t} \equiv E_t [\Omega_{t,t+1}] \left(R_t^* \frac{S_t}{F_t} - R_t \right) \quad (3.23)$$

$$\nu_{N,t} \equiv E_t [\Omega_{t,t+1}] R_t \quad (3.24)$$

for the stochastic discount factor of bank $\Omega_{t,t+1} \equiv \Lambda_{t,t+1}(1 - \sigma + \sigma\nu_{t+1})$.²⁷ Then, the Bellman equation is simplified as

$$\begin{aligned} \nu_t &= \max_{\phi_{H,i,t}, \phi_{X,i,t}} \nu_{H,t} \phi_{H,i,t} + \nu_{X,t} \phi_{X,i,t} + \nu_{N,t} \\ \text{s.t. } \nu_t &\geq \left[\left(\theta_{H1} + \theta_{H2} \frac{Q_t K_{H,t}}{P_t} \right) \phi_{H,i,t} + \left(\theta_{X1} + \theta_{X2} \frac{X_t}{P_t} \right) \phi_{X,i,t} \right] \end{aligned}$$

The first-order conditions of the above Bellman equation are

$$\nu_{H,t} = \mu_t \left(\theta_{H1} + \theta_{H2} \frac{Q_t K_{H,t}}{P_t} \right) \quad (3.25)$$

$$\nu_{X,t} = \mu_t \left(\theta_{X1} + \theta_{X2} \frac{X_t}{P_t} \right) \quad (3.26)$$

where μ_t is the Lagrangian multiplier of the leverage constraint. In contrast to frictionless asset pricing models, $\nu_{H,t}$ and $\nu_{X,t}$ are non-zero even up to first-order to the extent that θ_{H1} , θ_{H2} , θ_{X1} , θ_{X2} are non-zero because the calibration of this model in Section 4.1 guarantees $\mu_t > 0$.

Let us focus on (3.26), the FOC for the CIP arbitrage. Combining (3.23) and (3.26), we can obtain the relationship between CIP deviations and synthetic dollar funding as

$$-cid_t = \frac{\mu_t}{E_t[\Omega_{t,t+1}]} \left(\theta_{X1} + \theta_{X2} \frac{X_t}{P_t} \right)$$

This equation is the upward-sloping inverse supply function of synthetic dollar funding. When there is no limit on CIP arbitrage, *i.e.* $\theta_{X1} = \theta_{X2} = 0$, the supply function is perfectly elastic at zero

²⁷When there is a limit on leverage, the marginal net worth loosens the leverage constraint and provides additional value, creating a wedge between the SDF of households and banks.

CIP deviations. This is the case before regulations on non-risk-weighted assets were introduced. Otherwise, the elasticity of the supply function is finite and positive. As the leverage constraint becomes tighter and thus μ_t rises, the supply function becomes more inelastic.

In each period, with probability σ , banks continue operating with their net worth evolving according to (3.20). Meanwhile, exiting banks are filled with new banks with endowments transferred from households. Hence, the law of motion for the aggregate net worth is given by

$$N_{t+1} = \sigma \left[(R_{K,t+1} - R_t) \phi_{H,t} + \left(R_t^* \frac{S_t}{F_t} - R_t \right) \phi_{X,t} + R_t \right] N_t + (1 - \sigma) \xi (\phi_{H,t} + \phi_{X,t}) N_t \quad (3.27)$$

3.2.7 Monetary Policy

We assume the following Taylor rule type US monetary policy as

$$\frac{R_t}{\bar{R}} = \left(\frac{R_{t-1}}{\bar{R}} \right)^{\rho_R} \left(\frac{P_t}{P_{t-1}} \right)^{\phi_\pi (1 - \rho_R)} \epsilon_{R,t} \quad (3.28)$$

where $\bar{R}$ is the steady-state value for R_t , ρ_R is the interest rate smoothing parameter, and ϕ_π is the Taylor rule coefficient on inflation rate. Log of the disturbance term $\epsilon_{R,t}$ follows an AR(1) process

$$\log \epsilon_{R,t} = \rho_m \log \epsilon_{R,t-1} + \sigma_m \epsilon_{m,t} \quad (3.29)$$

for the US monetary policy shock $\epsilon_{m,t} \sim N(0, 1)$.

3.2.8 Fiscal Policy

The US government transfers TR_t to households and subsidizes firms to get rid of market power. This fiscal policy is described as the following:

$$TR_t + s \left(P_{H,t} Y_{H,t} + \frac{1}{S_t} P_{H,t}^* Y_{H,t}^* \right) = 0 \quad (3.30)$$

3.3 Non-US Economy

For the non-US economy, all sectors other than financial intermediaries are assumed to be identical to the US economy. See Appendix D for details. Here, I focus on financial intermediaries. Non-US variables are denoted with asterisk.

3.3.1 Financial Intermediary

As the US, there is a continuum of banks with total measure one and they exit with probability $1 - \sigma$ in each period. Given its net worth $N_{i,t}^*$, bank i takes deposits $D_{i,t}^*$ from non-US households. Also, there is lending from US banks $S_t \tilde{X}_{i,t}^*$ since they deposit for taking advantage of CIP arbitrage

opportunities.²⁸ Then, the total amount of deposits is $D_{i,t}^* + S_t \tilde{X}_{i,t}^*$. Note that non-US banks cannot issue deposits in US dollar, implying that direct dollar funding is not available to them. We will see the importance of this assumption below. From these sources of funding, bank i purchases non-US capital $K_{F,i,t}^*$ at the price of Q_t^* and US capital $K_{H,i,t}^*$ at Q_t . Then, the balance sheet identity of bank i is given by

$$Q_t^* K_{F,i,t}^* + S_t Q_t K_{H,i,t}^* = D_{i,t}^* + S_t \tilde{X}_{i,t}^* + N_{i,t}^*$$

In period $t + 1$, bank i earns gross return rate of $R_{K,t+1}^* \equiv (\tilde{R}_{K,t+1}^* + (1 - \delta)Q_{t+1}^*)/Q_t^*$ from $K_{F,i,t}^*$ and $R_{K,t+1}$ from $K_{H,i,t}^*$. With these returns and newly issued deposits $D_{i,t+1}^* + S_{t+1} \tilde{X}_{i,t+1}^*$, it purchases $K_{F,i,t+1}^*$ and $K_{H,i,t+1}^*$ and repays $R_t^*(D_{i,t}^* + S_t \tilde{X}_{i,t}^*)$.

The value of US capital holdings $Q_t K_{H,i,t}^*$ is denominated in USD while liabilities $D_{i,t}^* + S_t \tilde{X}_{i,t}^*$ are denominated in EUR, meaning that there is a currency mismatch between $K_{H,i,t}^*$ and liabilities. As we will see in (3.32), non-US banks optimally choose the amount of currency matching based on differential regulation on currency matching and uncovered open position.²⁹ Since direct dollar funding is assumed to be unavailable to non-US banks, synthetic dollar funding through FX swap markets is the only option for currency matching. This assumption is for simplifying the analysis and also not unrealistic because non-US banks, except for some big global banks, usually lack access to direct dollar funding or they need to pay high premium for the dollar funding (see Ivashina, Scharfstein, and Stein, 2015; Du and Schreger, 2022, for instance).³⁰ This is the important and distinguishing feature of the model that creates the channel through which CIP deviations affect cross-border capital flows and asset prices.

Let bank i 's demand for synthetic dollar funding be $x_{i,t}^* Q_t K_{H,i,t}^*$ for $x_{i,t}^* \in [0, 1]$. Then, in period $t + 1$, $\text{€} R_t^* S_t x_{i,t}^* Q_t K_{H,i,t}^*$ is exchanged into $\text{\$} R_t^* (S_t / F_t) x_{i,t}^* Q_t K_{H,i,t}^*$ by the forward leg of the FX swap contract. To sum up, the budget constraint expressed in terms of EUR is

$$\begin{aligned} Q_{t+1}^* K_{F,i,t+1}^* + S_{t+1} Q_{t+1} K_{H,i,t+1}^* + R_t^* (D_{i,t}^* + S_t \tilde{X}_{i,t}^*) + S_{t+1} R_t^* \frac{S_t}{F_t} x_{i,t}^* Q_t K_{H,i,t}^* \\ = R_{K,t+1}^* Q_t^* K_{F,i,t}^* + S_{t+1} R_{K,t+1} Q_t K_{H,i,t}^* + (D_{i,t+1}^* + S_{t+1} \tilde{X}_{i,t+1}^*) + R_t^* S_t x_{i,t}^* Q_t K_{H,i,t}^* \end{aligned}$$

Figure 5 summarizes the balance sheet and the flow of funds of non-US bank. Cash flows from the FX swap contract are described in the red box.

²⁸ $\tilde{X}_{i,t}^*$ is the total amount of lending from US banks that non-US bank i obtains, and it is not necessarily lending from US bank i .

²⁹ This approach enables us to use the first-order perturbation method unlike the mean-variance framework, and thus is easily applicable to standard business cycle models. Liao and Zhang (2020) derives the demand for currency hedging from mean-variance utility function in a two-period partial equilibrium framework.

³⁰ Non-US banks cannot usually tap US dollar from deposits. Wholesale dollar funding is also available for only top-tier global banks. Hence, non-US banks with low credit quality have to rely on synthetic dollar funding. See Rime, Schrimpf, and Syrstad (2022) for detailed explanation.

Balance Sheet		Flow of Funds	
Asset	Liability	t	$t + 1$
$Q_t^* K_{F,i,t}^*$	$D_{i,t}^*$	$-\epsilon Q_t^* K_{F,i,t}$	$+\epsilon R_{K,t+1}^* Q_t^* K_{F,i,t}^*$
$S_t Q_t K_{H,i,t}^*$	$S_t \tilde{X}_{i,t}^*$	$-\$ Q_t K_{H,i,t}$	$+\$ R_{K,t+1} Q_t K_{H,i,t}^*$
	$N_{i,t}^*$	$+\$ x_{i,t}^* Q_t K_{H,i,t}^*$	$-\$ R_t^* (S_t/F_t) x_{i,t}^* Q_t K_{H,i,t}^*$
		$-\epsilon S_t x_{i,t}^* Q_t K_{H,i,t}^*$	$+\epsilon R_t^* S_t x_{i,t}^* Q_t K_{H,i,t}^*$
		$+\epsilon S_t \tilde{X}_{i,t}^*$	$-\epsilon R_t^* S_t \tilde{X}_{i,t}^*$
		$+\epsilon D_{i,t}^*$	$-\epsilon R_t^* D_{i,t}^*$

Figure 5: Balance Sheet and Flow of Funds: Non-US Bank

Combining the balance sheet identity and the budget constraint, we can obtain the law of motion for net worth as

$$\begin{aligned}
N_{i,t+1}^* = & \left[(R_{K,t+1}^* - R_t^*) \phi_{F,i,t}^* + \underbrace{\frac{S_{t+1}}{S_t} \left(R_{K,t+1} - R_t^* \frac{S_t}{S_{t+1}} \right)}_{\textcircled{B}} (1 - x_{i,t}^*) \phi_{H,i,t}^* \right. \\
& \left. + \underbrace{\frac{S_{t+1}}{S_t} \left(R_{K,t+1} - R_t^* \frac{S_t}{F_t} \right)}_{\textcircled{C}} x_{i,t}^* \phi_{H,i,t}^* + R_t^* \right] N_{i,t}^* \quad (3.31)
\end{aligned}$$

for the ratio of each asset to net worth

$$\begin{aligned}
\phi_{F,i,t}^* &= \frac{Q_t^* K_{F,i,t}^*}{N_{i,t}^*} \\
\phi_{H,i,t}^* &= \frac{S_t Q_t K_{H,i,t}^*}{N_{i,t}^*}
\end{aligned}$$

In (3.31), each asset-to-net-worth ratio is multiplied by the excess return of the asset. $\textcircled{B}$ is the dollar return on $K_{H,i,t}^*$ in excess of EUR borrowing. Since the currency of return, USD, is not matched with the currency of cost which is EUR, the excess return in USD is subject to the exchange rate risk. On the other hand, $\textcircled{C}$ is the dollar return in excess of the synthetic dollar funding cost, implying that the currency of return and cost are matched.³¹ It can be expressed as $R_{K,t+1} - (R_t - cid_t)$, so $-cid_t$ is an intermediation fee that non-US banks pay for synthetic dollar funding.

³¹One may argue that the return rate in EUR is still subject to exchange rate risk as $\textcircled{C}$ is multiplied by the USD appreciation rate, and it needs to be fully hedged. However, this is infeasible since $R_{K,t+1}$ is unknown at period t . Thus, we cannot hedge $R_{K,t+1}$, and instead use return rate without uncertainty when deciding the amount of hedging. In this paper, risk-free rate R_t^* is used, and there is an hedging error $((F_t - S_{t+1})/S_t)(R_{K,t+1} - R_t^* S_t/F_t)$. This hedging error is small, about -0.013bp in the steady-state, and thus creates little problem since we are analyzing near the steady-state.

Let us denote continuing bank i 's objective function as $V_{i,t}^*$. Then, $V_{i,t}^*$ is defined recursively as

$$V_{i,t}^* = E_t \sum_{s=1}^{\infty} (1-\sigma)\sigma^{s-1} \Lambda_{t,t+s}^* N_{i,t+s}^* = E_t [\Lambda_{t,t+1}^* \{(1-\sigma)N_{i,t+1}^* + \sigma V_{i,t+1}^*\}]$$

Similar to the US, each bank is subject to a leverage constraint

$$V_{i,t}^* \geq \left[\left(\theta_{F1}^* + \theta_{F2}^* \frac{Q_t^* K_{F,t}^*}{P_t^*} \right) Q_t^* K_{F,i,t}^* + \left(\theta_{H1}^* + \theta_{H2}^* \frac{(1-x_t^*) S_t Q_t K_{H,t}^*}{P_t^*} \right) (1-x_{i,t}^*) S_t Q_t K_{H,i,t}^* \right. \\ \left. + \left(\theta_{X1}^* + \theta_{X2}^* \frac{x_t^* S_t Q_t K_{H,t}^*}{P_t^*} \right) x_{i,t}^* S_t Q_t K_{H,i,t}^* \right] \quad (3.32)$$

Here, θ_{H1}^* and θ_{X1}^* are parameters for the limit on unhedged and hedged US capital holdings. In our calibration, $\theta_{H1}^* > \theta_{X1}^*$, so unhedged US capital holdings are subject to tighter regulation.

Under the conjecture that $V_{i,t}^* = \nu_t^* N_{i,t}^*$, the optimization problem of continuing bank i is

$$\nu_t^* = \max_{\phi_{F,i,t}^*, \phi_{H,i,t}^*, x_{i,t}^*} \nu_{F,t}^* \phi_{F,i,t}^* + \nu_{H,t}^* (1-x_{i,t}^*) \phi_{H,i,t}^* + \nu_{X,t}^* x_{i,t}^* \phi_{H,i,t}^* + \nu_{N,t}^* \\ \text{s.t. } \nu_t^* \geq \left[\left(\theta_{F1}^* + \theta_{F2}^* \frac{Q_t^* K_{F,t}^*}{P_t^*} \right) \phi_{F,i,t}^* + \left(\theta_{H1}^* + \theta_{H2}^* \frac{(1-x_t^*) S_t Q_t K_{H,t}^*}{P_t^*} \right) (1-x_{i,t}^*) \phi_{H,i,t}^* \right. \\ \left. + \left(\theta_{X1}^* + \theta_{X2}^* \frac{x_t^* S_t Q_t K_{H,t}^*}{P_t^*} \right) x_{i,t}^* \phi_{H,i,t}^* \right]$$

for the stochastic discount factor of bank $\Omega_{t,t+1}^* \equiv \Lambda_{t,t+1}^* (1-\sigma + \sigma \nu_{t+1}^*)$ and the expected discounted returns on assets and net worth as

$$\nu_{F,t}^* \equiv E_t [\Omega_{t,t+1}^* (R_{K,t+1}^* - R_t^*)] \quad (3.33)$$

$$\nu_{H,t}^* \equiv E_t \left[\Omega_{t,t+1}^* \frac{S_{t+1}}{S_t} \left(R_{K,t+1}^* - R_t^* \frac{S_t}{S_{t+1}} \right) \right] \quad (3.34)$$

$$\nu_{X,t}^* \equiv E_t \left[\Omega_{t,t+1}^* \frac{S_{t+1}}{S_t} \left(R_{K,t+1}^* - R_t^* \frac{S_t}{F_t} \right) \right] \quad (3.35)$$

$$\nu_{N,t}^* \equiv E_t [\Omega_{t,t+1}^* R_t^*] \quad (3.36)$$

The first-order conditions for the above problem are

$$\nu_{F,t}^* = \mu_t^* \left(\theta_{F1}^* + \theta_{F2}^* \frac{Q_t^* K_{F,t}^*}{P_t^*} \right) \quad (3.37)$$

$$\nu_{H,t}^* = \mu_t^* \left(\theta_{H1}^* + \theta_{H2}^* \frac{(1 - x_t^*) S_t Q_t K_{H,t}^*}{P_t^*} \right) \quad (3.38)$$

$$\nu_{X,t}^* = \mu_t^* \left(\theta_{X1}^* + \theta_{X2}^* \frac{x_t^* S_t Q_t K_{H,t}^*}{P_t^*} \right) \quad (3.39)$$

where μ_t^* is the Lagrangian multiplier of the leverage constraint. In particular, (3.35) and (3.39) yield the inverse demand function for the synthetic dollar funding as

$$-cid_t = \frac{E_t \left[\Omega_{t,t+1}^* \frac{S_{t+1}}{S_t} (R_{K,t+1} - R_t) \right]}{E_t \left[\Omega_{t,t+1}^* \frac{S_{t+1}}{S_t} \right]} - \frac{\mu_t^*}{E_t \left[\Omega_{t,t+1}^* \frac{S_{t+1}}{S_t} \right]} \left(\theta_{X1}^* + \theta_{X2}^* \frac{x_t^* S_t Q_t K_{H,t}^*}{P_t^*} \right)$$

The demand for synthetic dollar funding $x_t^* Q_t K_{H,t}^*$ is decreasing in $-cid_t$ unless $\theta_{X1}^* = \theta_{X2}^* = 0$.

The law of motion for the aggregate net worth is

$$\begin{aligned} N_{t+1}^* = & \sigma \left[(R_{K,t+1}^* - R_t^*) \phi_{F,t}^* + \frac{S_{t+1}}{S_t} \left(R_{K,t+1} - R_t^* \frac{S_t}{S_{t+1}} \right) (1 - x_t^*) \phi_{H,t}^* \right. \\ & \left. + \frac{S_{t+1}}{S_t} \left(R_{K,t+1} - R_t^* \frac{S_t}{F_t} \right) x_t^* \phi_{H,t}^* + R_t^* \right] N_t^* + (1 - \sigma) \xi^* (\phi_{F,t}^* + \phi_{H,t}^*) N_t^* \end{aligned} \quad (3.40)$$

where ξ^* is the fraction of total assets provided as endowment for entrant banks.

3.4 Equilibrium

The market clearing condition for the FX swap market equates the demand and supply for synthetic dollar funding. US banks supply X_t as CIP arbitrageurs while non-US banks demand $x_t^* Q_t K_{H,t}^*$ for currency matching. Hence, the equilibrium condition is

$$X_t = x_t^* Q_t K_{H,t}^* \quad (3.41)$$

Figure 6 plots the downward-sloping demand and upward-sloping supply of synthetic dollar funding around the steady-state.

Combining the household and the bank budget constraint with the profit functions of the firms,

Figure 6: Demand and Supply Function of the FX Swap Market

Note. This figure shows the demand and supply functions for the synthetic dollar funding in the FX swap market. The solid red line is the demand function while the solid blue line is the supply function. These functions are evaluated around the steady-state.

we can obtain the US balance of payment equation as

$$TB_t + \left(R_{t-1}^* \frac{S_{t-1}}{F_{t-1}} - 1 \right) X_{t-1} - (R_{K,t} - 1) Q_{t-1} K_{H,t-1}^* = (X_t - Q_t K_{H,t}^*) - (X_{t-1} - Q_{t-1} K_{H,t-1}^*) \quad (3.42)$$

for the trade balance TB_t defined as

$$TB_t \equiv \left(1 - \frac{\psi_P}{2} \left(\frac{P_{H,t}}{P_{H,t-1}} - 1 \right)^2 \right) P_{H,t} Y_{H,t} + \left(1 - \frac{\psi_P}{2} \left(\frac{P_{H,t}^*}{P_{H,t-1}^*} - 1 \right)^2 \right) \frac{1}{S_t} P_{H,t}^* Y_{H,t}^* - P_t \left[C_t + I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1 \right)^2 \right) \right] \quad (3.43)$$

The LHS of (3.42) is the current account of the US, which consists of the trade balance and the income balance. The trade balance is the difference between the output (net of price adjustment costs) and the domestic absorption (net of investment adjustment costs). The income balance is the return on CIP arbitrage net of the return on US capital held by non-US. According to the balance of payment identity, the current account is equal to the change in US net foreign asset (NFA) position, which is the RHS of (3.42). Here, US NFA is given by $X_t - Q_t K_{H,t}^*$.

All equations characterizing the equilibrium are summarized in Appendix E.

4 Results

Based on the model in Section 3, I investigate effects of US monetary policy on CIP deviations, synthetic dollar funding, and implications for the transmission channel of US monetary policy. First, parameters of this model are calibrated to match long-run first moments of the US and the rest of the world. Then, impulse responses to a contractionary US monetary policy shock are derived. US monetary contraction lowers US banks' supply of synthetic dollar funding because it tightens the limit on CIP arbitrage. This leads to the widening of CIP deviations and lower synthetic dollar funding. Compared to the counterfactual case where CIP always holds, spillovers and spillbacks to output, investment, and inflation are amplified due to the widening of CIP deviations.

4.1 Calibration

Table 3 presents calibrated parameters of the model in quarterly frequency. First, in the household side, the discount factor $\beta = \beta^*$ is given by 0.99 to produce 4% annual risk-free rate while the inverse of intertemporal elasticity of substitution γ is 2 following the standard literature. The elasticity of substitution ν between domestic and imported goods is calibrated as 3.8 following [Bajzik et al. \(2020\)](#). On the other hand, the elasticity of substitution ϵ between varieties within each country is 6 following the standard literature. Since developed countries show strong home bias, ω is calibrated as 0.8. φ , which is the inverse of Frisch elasticity, is set to be 1, and disutility of labor κ and κ^* are calibrated to match the steady-state labor 1/3.

For the firm parameters, subsidy s and s^* are set at 0.2 to eliminate the steady-state price distortion while the capital share α is given by a standard value of 1/3. The Rotemberg price adjustment cost ψ_P is calibrated as 155.88 in order to match the Calvo parameter of 0.84.³² Capital depreciation rate δ is set at 0.04 while the investment adjustment cost ψ_I is set at 0.7.

Parameters of the financial intermediaries are calibrated to match several long-run first moments of the US and the non-US. First, σ , which is the survival rate of banks, is given by 0.95 to match the average survival horizon of 5 years. ξ and ξ^* are calibrated as 0.117 and 0.090 respectively to match the steady-state US and non-US banks' leverage of 6. The main financial friction parameters θ_{H1} , θ_{X1} , θ_{F1}^* , θ_{H1}^* , and θ_{X1}^* are calibrated by targeting the following five empirical moments at annual frequency simultaneously: excess return on US capital of 100bp, excess return on non-US capital of 100bp, US NFA-to-GDP ratio of -43.9%, non-US banks' domestic investment share of 54%, and post-GFC CIP deviations of -21bp. Excess returns on capital $R_K - R$ and $R_K^* - R^*$ are long-run average credit spreads, which include not only equity returns but also corporate bond yields and commercial paper rates. The steady-state value of this excess return on bank assets is set at 1pp following [Akinci, Şebnem Kalemli-Özcan, and Queralto \(2022\)](#). Net foreign asset position in

³²[Corsetti, Dedola, and Leduc \(2008\)](#) show that the Rotemberg parameter ψ_P corresponds to $(\epsilon - 1)\lambda / (1 - \lambda)(1 - \beta\lambda)$ for the Calvo parameter λ .

this model is $X - x^*QK_H^*$, so the third empirical moment targets $(X - x^*QK_H^*)/(4 * P_H * Y)$. As non-US banks' asset portfolios consist of US and non-US capital, its domestic investment share is $Q^*K_F^*/(Q^*K_F^* + SQK_H^*)$. The steady-state domestic investment share of 54% is from [Camanho, Hau, and Rey \(2022\)](#) who analyzed fund-level data from FactSet for the period 1999-2015. Post-GFC CIP deviation of -21bp comes from the average of 3-month LIBOR basis of G10 currencies for the period 1/1/2008 to 4/30/2021.

The quadratic parameters θ_{H2} , θ_{X2} , θ_{F2}^* , θ_{H2}^* , θ_{X2}^* are introduced to solve the indeterminacy problem in a portfolio balance model with incomplete markets. This is similar to the external debt-elastic interest rate in [Schmitt-Grohé and Uribe \(2003\)](#) for solving the indeterminacy problem in a small open economy model with incomplete markets. Following [Devereux, Engel, and Wu \(2023\)](#), all parameters θ_{H2} , θ_{X2} , θ_{F2}^* , θ_{H2}^* , and θ_{X2}^* are set at a low value of 0.005. In Appendix I, I conduct a sensitivity analysis showing that the results of the model are not driven by the choice of these quadratic parameters.

Regarding the monetary policy, ϕ_π is 1.5 following the standard New Keynesian literature such as [Galí \(2015\)](#). Interest rate smoothing parameters ρ_r and ρ_r^* are assumed to be 0.7 while the persistence of monetary policy shocks ρ_m and ρ_m^* are 0.25. The standard deviations σ_m and σ_m^* of monetary policy shocks are given by 0.25% to produce 1% annual standard deviation.

Detailed explanations for the calibration and the steady-state of the model can be found in Appendix F.

Table 3: Parameter Values

Parameter	Value	Description	Source or Target
$\beta = \beta^*$	0.99	Discount factor	4% risk-free rate
γ	2	Inverse of intertemporal elasticity of substitution	Standard literature
ω	0.8	Home bias	Standard literature
ν	3.8	Elasticity of substitution across country	Bajzik et al. (2020)
ϵ	6	Elasticity of substitution within country	Standard literature
φ	1	Inverse of Frisch elasticity	Standard literature
κ	13.97	US Disutility of labor	Steady-state L of 1/3
κ^*	11.83	Non-US Disutility of labor	Steady-state L^* of 1/3
$s = s^*$	0.2	Subsidy to firms	$s = 1/(\epsilon - 1)$
α	1/3	Capital share	Standard literature
ψ_P	155.88	Rotemberg price adjustment cost	Calvo parameter of 0.84
δ	0.04	Capital depreciation rate	Standard literature
ψ_I	0.7	Investment adjustment cost	Standard literature
σ	0.95	Survival rate of banks	Average survival horizon of 5 years

4.2 Impulse Responses

Based on the calibrated model, I produce impulse responses to 1pp contractionary US monetary policy shock. Figure 7 displays impulse responses of interest rates, CIP deviations, forward premium with reasons for the response in CIP deviations. Time periods in the x-axis are in quarterly frequency, and the impulse responses are shown up to 5 years. In response to 1pp US monetary policy shock in panel (7a), US nominal interest rate rises initially in panel (7b), with some decreases along the way to lower inflation rate and high persistence in policy rate.

The main mechanism of the synthetic dollar funding channel works through the effect of US monetary policy on CIP deviations. First, panel (7c) shows that CIP deviations decline about 30bp from their steady-state in the baseline economy. Since CIP deviations are negative (-21bp) in the steady-state, the decline in CIP deviations is equivalent to the widening of CIP deviations. After about 10 quarters, CIP deviations return to their steady-state level of -21bp. Panel (7d) shows that forward premium $\rho_t \equiv \log F_t - \log S_t$ declines about 106bp. Since $cid_t \approx \log R_t - \log R_t^* + \rho_t$, this means that ρ_t is the main variable leading to the widening of CIP deviations. This is in line with the observation in Appendix A.3 that most of the responses in CIP deviations to US monetary policy shock comes from the responses in forward premium.

CIP deviations widen due to the decrease in net worth of US banks and the resulting tighter limit on CIP arbitrage. In panel (7e), net worth of US banks decreases in response to the contractionary US monetary policy shock. If the US policy rate rises, the aggregate demand of the US is reduced, exerting downward pressure on the price of the US capital. As US banks hold US capital, the asset values of their balance sheets go down, lowering their net worth. In panel (7f), the Lagrangian multipliers of US banks rise about 1.5 log points. This means that the leverage constraints of US banks are tightened due to their lower net worth. As implied by the supply function of FX swap (3.26), the increase in the Lagrangian multiplier of the US bank leads to the widening of CIP deviations.

Next, I investigate how the widening of CIP deviations affects impulse responses of other macroeconomic variables. For this purpose, the baseline impulse responses are compared with counterfactual impulse responses without limit on CIP arbitrage, *i.e.* $\theta_{X1} = \theta_{X2} = 0$. This counterfactual setting models the economy where CIP always holds, which is the case in the pre-GFC period. All other parameters of the counterfactual economy are set to be the same as the baseline model in order to focus on differences in impulse responses only due to CIP deviations coming from the limit on CIP arbitrage. In all figures, red solid lines are baseline impulse responses while black dotted lines are counterfactual ones.

Figure 8 presents impulse response of global capital flows mediated by US and non-US banks. First, as in panel (8a), synthetic dollar funding decreases in response to a contractionary US monetary policy shock. Since US monetary contraction leads to higher λ_t , the supply schedule of synthetic

Figure 7: Impulse Responses to 1pp US Monetary Policy Shock: CIP Deviations

Note. This figure shows quarterly impulse responses to 1pp contractionary US monetary policy shock. Each impulse response is the deviation from the steady-state. $\log \epsilon_{R,t}$ is the US monetary policy shock, R_t is the US nominal interest rate, cid_t is the CIP deviation, ρ_t is the forward premium, N_t/P_t is the real net worth of US banks, and λ_t is the Lagrangian multiplier of US banks' leverage constraints.

dollar funding decreases in the baseline economy.³³ Interestingly, there is a stark difference in the counterfactual impulse response which shows an increase in the synthetic dollar funding. This is due to the change in the composition of assets held by US banks. Since there is no regulation on FX swap, US banks substitute FX swap for US capital holdings, which results in the increasing synthetic dollar funding in the counterfactual economy.

Then, $K_{H,t}^*$ declines by about 0.8% on impact, reaching a trough of 1.4% after 7 quarters, as shown in panel (8b). This is much larger than the counterfactual impulse response of 0.8% at the trough, implying significant amplification of the decrease in cross-border positions by the non-US. The main reason for this amplification is the decrease in synthetic dollar funding. As non-US banks desire to hedge currency risks in holding US capital, they demand X_t . The widening of CIP deviations and lower demand for X_t amplifies the decrease in $K_{H,t}^*$ compared to the conventional effect without CIP deviations. On the other hand, $K_{H,t}$ shows a persistent increase with an impact response of 3.7%, which stands in stark contrast to the decrease observed in the counterfactual economy. These predictions are in line with the role of US monetary policy in the global retrenchment of international capital flows (Miranda-Agrippino and Rey, 2020).

Figure 8: Impulse Responses to 1pp US Monetary Policy Shock: Capital Flows

Note. This figure shows quarterly impulse responses to 1pp contractionary US monetary policy shock. Each impulse response is the deviation from the steady-state. In each panel, red solid line is the baseline impulse response while the black dotted line is the counterfactual impulse response without limit on CIP arbitrage. X_t/P_t is the real synthetic dollar funding, $K_{H,t}^*$ is US capital holdings by non-US banks, and $K_{H,t}$ is US capital holdings by US banks.

In Figure 9, we can see the role of CIP deviations and synthetic dollar funding in spillovers to the non-US as well as spillbacks to the US. First, panel (9a) and (9b) show the impulse responses of the aggregate US capital K_t and non-US capital K_t^* . K_t decreases by 0.9% at its trough in the baseline economy while the counterfactual decrease is about 0.8%. The amplification of 0.1pp is due to the widening of CIP deviations and the resulting reduction in synthetic dollar funding. As we have seen in Figure 8, synthetic dollar funding X_t and non-US banks' cross-border asset holdings $K_{H,t}^*$ decrease more when CIP does not hold. Although $K_{H,t}$ is higher under the baseline economy,

³³In Appendix G, we can see that λ_t^* also increases in response to US monetary contraction, resulting in the decrease in the demand for synthetic dollar funding. The supply-side effect is larger than the demand-side effect in the general equilibrium effect so that CIP deviations widen and synthetic dollar funding decreases.

the total amount of capital $K_t = K_{H,t} + K_{H,t}^*$ is lower because the share of $K_{H,t}^*$ is about 86% in the steady-state. On the other hand, K_t^* goes down by 0.4%, with the amplification of 0.1pp compared to the counterfactual impulse response. This is due to larger intermediation fees—CIP deviations—that non-US banks have to pay for currency matching. Even though CIP deviations are not directly related to non-US capital holdings, larger CIP deviations yields lower net worth of non-US banks, which leads to the larger reduction in K_t^* than the counterfactual economy.

Similar to capital stocks, impulse responses of US output Y_t and non-US output Y_t^* are amplified in the presence of the limit on CIP arbitrage. In the baseline economy, Y_t declines by 1.2% while Y_t^* is reduced by 0.8%. Compared to the counterfactual without CIP deviations, the amplification effect is about 15-20% with persistence; this is non-trivial considering that CIP deviations widen by 30bp in response to 1pp US monetary policy shock. The reason for the amplification effect is similar to the capital stock: the widening of CIP deviations. Since the widening of CIP deviations make the aggregate capital be lower, Y_t and Y_t^* also become lower. Investments, inflation, and exchange rates show similar patterns. See [Appendix G](#) for details.

Figure 9: Impulse Responses to 1pp US Monetary Policy Shock

Note. This figure shows quarterly impulse responses to 1pp contractionary US monetary policy shock. Each impulse response is the deviation from the steady-state. In each panel, red solid line is the baseline impulse response while the black dotted line is the counterfactual impulse response without limit on CIP arbitrage. K_t is US capital, K_t^* is non-US capital, Y_t is US output, and Y_t^* is non-US output.

5 Central Bank Swap Lines and Synthetic Dollar Funding Channel

In this section, I analyze how central bank swap lines affect the synthetic dollar funding channel of US monetary policy. Since central bank swap lines impose ceiling on CIP deviations, the widening of CIP deviations in response to US monetary contraction is prevented. Hence, the synthetic dollar funding channel is attenuated compared to the baseline economy without the swap line policy.

5.1 Overview of Central Bank Swap Lines

Central bank swap lines are liquidity facilities for stabilizing international financial markets during the financial turmoil such as the GFC and the Covid-19 crisis.³⁴ Figure 10 describes flow of funds through central bank swap lines. As a lender of last resort, a source central bank lends its currency to a recipient central bank while the recipient currency is pledged as a collateral. Then, the recipient central bank lends the source currency to banks in its jurisdiction with collateral pledged, usually at similar terms as domestic discount window lending. Considering the major role of the US dollar, the source central bank is referred to as the Federal Reserve (Fed) and the recipient central bank is referred to as the European Central Bank (ECB).

Figure 10: Flow of Funds through Central Bank Swap Lines

Note. This figure shows flow of funds through central bank swap lines. In line with previous notations, the source currency is denoted as USD (\$) while the recipient currency is denoted as EUR (€).

The main policy instrument of central bank swap lines is the swap spread, a spread over a risk-free rate such as an overnight index swap rate, that the source central bank imposes on swap lending.³⁵ According to Bahaj and Reis (2022), the swap line spread ss_t works as an upper bound on CIP deviations: $-cid_t \leq ss_t$.³⁶ The intuition for this inequality comes from the no-arbitrage condition.³⁷ $R_t - cid_t$ is the synthetic dollar funding cost while $R_t + ss_t$ is the cost of dollar funding

³⁴During the Covid-19 crisis, repo lines were introduced. Repo lines are different from swap lines in terms of collateral and eligibility. For example, repo lines require securities denominated in the source currency, such as US treasuries, as collateral. In this paper, I will focus on the swap line policy for simplicity.

³⁵Maturities of swap lines are mostly overnight, 1-week, and 1-month in practice, with the maximum of 3-month. Limits are also specified in swap line arrangements, unlimited for the standing facilities with Bank of Canada, European Central Bank, Bank of England, Bank of Japan, and Swiss National Bank. See Bahaj and Reis (2023) for details.

³⁶In Bahaj and Reis (2022), the original inequality is $-cid_t \leq ss_t + (r_t^{p*} - r_t^{\nu*})$ for cid_t measured using OIS rates as (net) risk-free rates, r_t^{p*} as the EU (net) policy rate, and $r_t^{\nu*}$ as the interest on excess reserves of ECB. $r_t^{\nu*} - r_t^{p*}$ is additional opportunity cost of synthetic dollar funding since EU banks give up excess return on reserves $r_t^{\nu*} - r_t^{OIS*}$ with adjustment of interest rate risks by $r_t^{OIS*} - r_t^{p*}$. This paper ignores this term because there is only one short-term rate in the model.

³⁷Even when the no-arbitrage condition is violated, the less restrictive version of the inequality holds. For more details, see Bahaj and Reis (2022).

through swap lines. If $R_t - cid_t > R_t + ss_t$, all EU banks will tap dollar swap lines and lend the dollar through FX swap markets, obtaining arbitrage profits. Note that transaction in the opposite direction cannot happen since EU banks cannot lend to the Fed through swap lines. Thus, by no-arbitrage condition, $-cid_t \leq ss_t$ should be satisfied. In this regard, the swap line policy can be seen as an international version of the discount window policy where the discount rate serves as a ceiling on the federal funds rate.

When central bank swap lines exist, then CIP deviations may not widen due to the ceiling imposed by swap lines. Then, the synthetic dollar funding channel can also be affected, even though there is no direct relationship between the conventional monetary policy controlling the short-term interest rate and the swap line policy controlling the swap spread over the short-term rate. In order to investigate whether the swap line policy affects the transmission channel of conventional monetary policy, this section compares impulse responses with and without central bank swap lines.

5.2 Model

First, the swap line policy is modeled as the following occasionally binding ceiling on $-cid_t$:

$$-cid_t \leq ss_t \quad (5.1)$$

Based on the swap spreads of standing facilities, ss_t is set at 25 basis points. Note that (5.1) is an occasionally binding constraint since the steady-state value of $-cid_t$ is 21 basis points. It binds only if CIP deviations widen more than the swap spread. If (5.1) does not bind, then swap lines are not used by non-US banks because swap lines are more expensive than private FX swaps.

Let us define the amount of dollar swap lending as X_t^{SL} . Then, the market clearing condition for the FX swap market is given by

$$X_t + X_t^{SL} = x_t^* Q_t K_{H,t}^* \quad (5.2)$$

Due to the ceiling on CIP deviations, there can be an excess demand for synthetic dollar funding. X_t^{SL} provided by the US government fills the excess demand and clears the FX swap market. In response to a contractionary US monetary policy shock, the supply function of synthetic dollar funding decreases. Without the swap line policy, CIP deviations would rise and synthetic dollar funding would decrease. However, since the swap line policy imposes a ceiling, CIP deviations do not rise. Instead, there is an excess demand for synthetic dollar funding, filled by swap lines X_t^{SL} .

This paper assumes that the US government lends X_t^{SL} to the non-US while getting repaid with the gross interest rate of $R_t - cid_t$ in the next period. Then, the government budget constraint

becomes³⁸

$$s \left(P_{H,t} Y_{H,t} + \frac{1}{S_t} P_{H,t}^* Y_{H,t}^* \right) + tr_t + X_t^{SL} = (R_{t-1} - cid_{t-1}) X_{t-1}^{SL} \quad (5.3)$$

Finally, the complementary slackness condition is given by

$$(cid_t + ss_t) X_t^{SL} = 0 \quad (5.4)$$

When (5.1) does not bind, then there is no excess demand for synthetic dollar funding and swap lines are not used, *i.e.* $X_t^{SL} = 0$. On the other hand, if $X_t^{SL} > 0$, then the ceiling should bind.

5.3 Impulse Responses

The model with the occasionally binding swap line policy is solved by the piecewise linear method in Guerrieri and Iacoviello (2015). Then, we compare the transmission channel of US monetary policy with and without central bank swap lines. For this purpose, I derive impulse responses to 1pp contractionary US monetary policy shock in each case. Impulse responses with swap lines are displayed in red solid line while impulse responses without swap lines are in black dotted line.

Impulse responses of CIP deviations and (real) swap line lending are displayed in Figure 11. Without central bank swap lines, which is the baseline case in Section 4.2, cid_t widens by around 30bp in response to 1pp US monetary policy shock. However, when there are central bank swap lines, the widening of CIP deviations is allowed only up to 4bp since $ss_t = 25bp$ and the steady-state $cid_t = 21bp$. This means that (5.1) binds on impact when US monetary policy tightens, leading to the impact response of 4bp in panel (11a).³⁹ Panel (11b) shows the impulse response of dollar swap lending. When (5.1) binds, $X_t^{SL} > 0$, and it goes back to the steady-state level of 0 when (5.1) starts to be non-binding. Obviously $X_t^{SL} = 0$ when there are no central bank swap lines.

Next, in Figure 12, effects of central bank swap lines on the transmission channel of US monetary policy are investigated. First, panel (12a) shows that the total synthetic dollar funding $X_t + X_t^{SL}$ is larger after 6 quarters when there are central bank swap lines. The puzzling part is the larger decrease in $X_t + X_t^{SL}$ before 6 quarters. This is due to the two different forces, offsetting each other, in the swap line policy: smaller CIP deviations versus lump-sum tax. In (5.3), we can see that X_t^{SL} is financed by lump-sum tax. Due to this lump-sum tax, US households have less resources for deposits, ultimately hampering intermediation activities of US banks in the FX swap market. This crowding out effect of public provision of US dollar is large enough until 6 quarters to reduce the

³⁸In practice, the Fed is the lender of dollar swap lines. Since there is no balance sheet of the Fed in this paper, it is assumed that the US government conducts swap lines instead.

³⁹In panel (11a), the number of periods under the binding regime of (5.1) is different from the number of periods that CIP deviations without swap lines are bigger than the swap spread. This is due to the difference in expectation for the duration of the binding regime.

Figure 11: Impulse Responses With and Without Swap Lines: CIP Deviations

Note. This figure shows quarterly impulse responses to 1pp contractionary US monetary policy shock. Each impulse response is the deviation from the steady-state. In each panel, red solid line is the impulse response with swap lines while the black dotted line is the impulse response without swap lines. cid_t is the CIP deviation and X_t^{SL}/P_t is the real swap line lending.

total synthetic dollar funding. After 6 quarters, the larger demand for $X_t + X_t^{SL}$ from smaller CIP deviations outweighs the negative effect from lump-sum tax. This response of $X_t + X_t^{SL}$ leads to the similar impulse response of $K_{H,t}^*$ in panel (12b).

Unlike capital flows, in panel (12c) and (12d), decreases in the US and the non-US aggregate capital are attenuated across all periods when there are central bank swap lines. Y_t and Y_t^* show similar patterns in panel (12e) and (12f). From these observations, we can say that the global transmission channel of US monetary policy to macro aggregates is dampened when there are central bank swap lines.

Note that this section does not deal with the optimal central bank swap line policy or optimal policy mix. Instead of a normative analysis, this section conducts a positive analysis focusing on how the transmission channel of US monetary policy changes when there are central bank swap lines. This positive analysis is more relevant in this paper since this model cannot deal with detriments of the swap line policy such as moral hazard problem. Moreover, the swap line policy is usually for stabilizing international financial markets during financial distress periods. Coordination with monetary policy for managing business cycles is outside the realm of the swap line policy.

Another related caveat is that we cannot say that the swap line policy is beneficial or detrimental for the conventional monetary policy. When there is a limit on CIP arbitrage and CIP deviations emerge as a consequence, effects of US monetary policy on inflation and output are amplified. It can be said that the swap line policy reduces this amplification. However, as long as we do not conduct welfare analysis, this paper does not speak to the desirability of the swap line policy for the implementation of the conventional monetary policy.

Figure 12: Impulse Responses With and Without Swap Lines: Macro Variables

Note. This figure shows quarterly impulse responses to 1pp contractionary US monetary policy shock. Each impulse response is the deviation from the steady-state. In each panel, red solid line is the baseline impulse response while the black dotted line is the counterfactual impulse response without limit on CIP arbitrage. $K_{H,t}^*$ is US capital holdings by non-US banks, $K_{H,t}$ is US capital holdings by US banks, K_t is US capital, K_t^* is non-US capital, Y_t is US output, and Y_t^* is non-US output.

6 Conclusion

This paper investigates effects of US monetary policy on CIP deviations and introduces a new transmission channel of US monetary policy through FX swap markets.

First, I empirically show that a tightening of US monetary policy widens CIP deviations in the post-GFC period. CIP deviations are measured as 3-month IBOR-bases of G10 currencies, and US monetary policy shocks are identified by the high-frequency method. By regressing CIP deviations on US monetary policy shocks in the post-GFC period, I find that a 1pp rise in US policy rate leads to a 35bp widening of CIP deviations.

Next, this paper develops a two-country New Keynesian model incorporating the FX swap market to explain the empirical results and explore their implications for the transmission channel. In the model, US and non-US banks participate in the FX swap market. US banks supply synthetic dollar funding by engaging in CIP arbitrage, with CIP deviations arising due to limits on this arbitrage. Non-US banks demand synthetic dollar funding for currency matching, paying CIP deviations as intermediation fees. The equilibrium CIP deviations are determined by the market-clearing condition in the FX swap market.

Then, I examine the impulse responses to a contractionary US monetary policy shock and compare them with the counterfactual scenario where there is no limit on CIP arbitrage. In response to a 1pp shock, CIP deviations widen by 30bp due to tighter leverage constraints on US banks. As the shadow cost of balance sheet space increases, US banks require larger CIP deviations to engage in arbitrage. Compared to the counterfactual impulse response, non-US banks' US capital holdings decrease more because they face higher synthetic dollar funding costs. Consequently, spillovers are amplified as non-US banks pay higher intermediation fees, while spillbacks are also amplified due to the larger reduction in non-US banks' demand for US capital.

Finally, this paper studies the effects of central bank swap lines on the synthetic dollar funding channel. The swap line policy is modeled as an occasionally binding constraint on CIP deviations. Since the swap line policy impose ceilings on CIP deviations, the widening of CIP deviations is reduced. Accordingly, the swap line policy dampens the synthetic dollar funding channel.

For future research, this paper can contribute to the normative analysis on central bank swap lines. Since the GFC, and particularly during the COVID-19 crisis, central bank swap lines have been widely used. However, the optimal design of the swap line policy remains an understudied area. [Lee \(2024\)](#) theoretically explores the optimal swap line policy for financial stability but does not provide quantitative guidelines. This paper can be extended to derive the optimal swap line policy quantitatively, allowing for an evaluation of the (sub)optimality of the current policy framework.

Appendix A Additional Empirical Analyses

A.1 Effects of US Monetary Policy Shock on CIP deviations: All Maturities

Table A.1 displays β_h of the regression (2.1) for each maturity h , denoted as 3M, 1Y, 2Y, 3Y, 5Y, 7Y, and 10Y. For each maturity, there are two columns: the left column is the estimation result when *NS* is used as the US monetary policy shock whereas the right column is the result when *Target* and *Path* are used as proxies for the shock. In order to consider cross-sectional dependence across G10 currencies, Driscoll-Kraay standard errors are reported in the parentheses unless the cross-sectional dependence is estimated to be weak by the test of Pesaran and Xie (2021). In that case, standard errors clustered at the level of currency are reported. N is the number of observations used in the estimation.

We can see that the size of β_h is smaller for longer-term maturities; the US monetary policy has less effects on longer-term CIP deviations. Appendix A.2 analyzes the term structure of β_h by conducting principal component analysis on CIP deviations across maturities. The first principal component is the level factor while the second principal component is the slope factor with factor loadings decreasing over maturities. Since a contractionary US monetary policy shock is shown to decrease both the level and the slope factor, the slope factor amplifies decreases in the level factor in short-term maturities while it dampens those in long-term maturities, leading to the term structure observed in Table A.1.

A.2 Term Structure of Effects of US Monetary Policy on CIP Deviations

In order to analyze the term structure of the effects of US monetary policy on CIP deviations, the relationship between principal components of CIP deviations and the US monetary policy is investigated. First, principal components (PCs) are extracted from Δcid across maturities for each currency. For instance, from the seven series of Australian Dollar CIP deviations consisting of maturities from 3-month to 10-year, I extract principal components. These factors summarize the information in Δcid across maturities. From Table A.2, we can see that the first two PCs explain about 58.5% - 87.6% of the variations in the changes in CIP deviations. For this reason, I will focus on the first two factors: PC1 and PC2.

Table A.3 displays factor loadings on PC1 and PC2 for each currency and each maturity. The upper panel of Table A.3 reports the factor loadings on PC1 while the factor loadings on PC2 are reported in the lower panel. Each column indicates factor loadings for each currency while each row reports loadings for each maturity. In the upper panel, loadings on PC1 are relatively constant across maturities for all currencies. This means that PC1 moves Δcid across all maturities similarly. On the other hand, loadings on PC2 have “slope” in the sense that loadings of short-term bases are high and positive while those of long-term bases are low and negative. A decrease in PC2 then leads to

Table A.1: Effects of US Monetary Policy Shock on CIP deviations: All Maturities

N	1031	1031	1039	1039	1024	1024		

Note. This table presents the regression results of CIP deviations on 1pp contractionary US monetary policy shock for each maturity of 3-month, 1-year, 2-year, 3-year, 5-year, 7-year, and 10-year. For each maturity, there are two columns: the left column is the estimation result when *NS* is used as the US monetary policy shock whereas the right column is the one when *Target* and *Path* are used as proxies for the shock. Units of the estimates are in basis points. Driscoll-Kraay standard errors are reported in the parentheses unless the cross-sectional dependence is weak. If the cross-sectional dependence is weak, standard errors clustered at the currency level are reported instead. *N* denotes the number of observations of the regression respectively. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

the decline in short-term Δcid and the rise in long-term Δcid . Following the terminology used in finance literature, PC1 and PC2 will be referred to as level factor and slope factor respectively.

Next, PC1 and PC2 are regressed onto the US monetary policy shock respectively. Since we have principal components for each currency, we can run OLS regressions with currency fixed effects similar to (2.1) as

$$PC1_{j,t} = \alpha_j + \beta \Delta mp_t + \epsilon_{j,t}$$

$$PC2_{j,t} = \alpha_j + \beta \Delta mp_t + \epsilon_{j,t}$$

Table A.4 shows the estimation results of the above regressions. Column (1) and (2) are the results for PC1 as the dependent variable while column (3) and (4) are the case of PC2 as the dependent variable. For each dependent variable PC1 and PC2, the left column is the result when *NS* is used as the monetary policy shock while the right column is the one with *Target* and *Path* as monetary

Table A.2: Cumulative Explained Variance of Δcid

Δcid	PC1	PC2	PC3	PC4	PC5
AUD	0.5619	0.7057	0.8214	0.9001	0.9444

Note. This table presents factor loadings on the first two principal components for each currency. The first panel shows the factor loadings on the first principal component while the second panel displays those on the second principal component. Each column indicates factor loadings for each G10 currency. In a column, elements are factor loadings for each maturity from 3-month to 10-year.

policy shocks. Note that the unit of the estimates has no meaning since the dependent variables are principal components.

In Table A.4, *NS* and *Target* are estimated to have significantly negative effect on PC2, and its effect on PC1 is also negative although it is insignificant. As the baseline estimation results, *Path* has insignificant effect on both PC1 and PC2. Hence, in response to the contractionary monetary policy shock, both the level and the slope factor decrease. Since PC1 is a level factor and the factor loadings

are positive, Δcid declines in response to the contractionary US monetary policy shock across all maturities. On the other hand, short-term Δcid decreases while long-term increases following the contractionary shock because PC2 is the slope factor. Recall that loadings on short-term bases are positive while those on long-term bases are negative. Combining these two observations, the decline in short-term Δcid is amplified while the decline in long-term Δcid is dampened due to the two offsetting forces. This makes β_h more negative for short-term CIP deviations and nearly zero for long-term CIP deviations, which sheds light on the term structure of β^h .

Table A.4: Principal Components of Δcid and the US Monetary Policy

	PC1		PC2	
	(1)	(2)	(3)	(4)
NS	-1.231 (1.925)		-5.991** (2.309)	
Target		-0.405 (1.297)		-4.939*** (1.059)
Path		-0.952 (1.413)		-0.979 (0.564)
R^2	0.001	0.001	0.082	0.131
N	1002	1002	1002	1002

Note. This table presents the regression results of principal components of Δcid on 1%p contractionary US monetary policy shock. For each principal component, there are two columns: the left column is the estimation result when *NS* is used as the US monetary policy shock whereas the right column is the one when *Target* and *Path* are used as proxies for the shock. Driscoll-Kraay standard errors are reported in the parentheses unless the cross-sectional dependence is weak. If the cross-sectional dependence is weak, standard errors clustered at the currency level are reported instead. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

A.3 Decomposition of the effect of US Monetary Policy on CIP Deviations

We can decompose the effect of the US monetary policy shock on LIBOR-based CIP deviations further since CIP deviations are given by $cid_{j,h,t} = r_{\$,h,t} - (r_{j,h,t} - \rho_{j,h,t})$. From the definition of CIP deviations, the effect on CIP deviations can be decomposed into the effect on the US LIBOR, (negative of) the currency j IBOR, and the forward premium. Table A.5 displays the decomposition for *NS*, *Target*, and *Path* respectively.

In Table A.5, there are three panels showing the decomposition for each monetary policy shock: top panel for *NS*, middle panel for *Target*, and bottom panel for *Path*. In each panel, the top row Δcid indicates the total effect which is equivalent to the baseline estimates in Table 2. The three rows below Δcid are the decomposed effects which sum up to the total effect. Driscoll-Kraay standard errors are reported in the parentheses unless the cross-sectional dependence is weak. If the cross-sectional dependence is weak, standard errors clustered at the currency level are reported instead.

First, US LIBOR $\Delta r_{\$}$ reacts less than one-to-one in response to the US monetary policy shock, implying imperfect pass-through of the US monetary policy on interbank rates. On the other hand, changes in synthetic dollar funding costs $\Delta r_j - \Delta \rho_j$ mostly come from forward premium $\Delta \rho_j$. This makes sense because the interbank rates of other countries which are affected by those countries' policy would be less connected to the US monetary policy than the US LIBOR is. Note that this decomposition is just an accounting exercise, and does not provide causal explanation that changes in synthetic dollar funding cost come from FX swap market frictions. According to [Du, Tepper, and Verdelhan \(2018\)](#), CIP deviations have emerged due to FX swap market frictions such as limit on arbitrage since the GFC.

Table A.5: Decomposition of the Effect of US Monetary Policy Shock on LIBOR-Basis

Note. This table presents the decomposition of effects of US monetary policy on CIP deviations. The top panel is the decomposition for *NS*, the medium panel is for *Target*, and the bottom panel is for *Path*. In each panel, the top row shows the total effect of which estimates are from the baseline regression shown in Table 2. The below three rows are decomposed effects respectively, and they sum up to the total effect. Units of the estimates are in basis points. Driscoll-Kraay standard errors are reported in the parentheses unless the cross-sectional dependence is weak. If the cross-sectional dependence is weak, standard errors clustered at the currency level are reported instead. *N* denotes the number of observations of the regression respectively. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Appendix B Robustness Check

In this section, I show that empirical results in Section 2 are robust to different choices of the dependent variable and the explanatory variable. For the dependent variable, I consider two-day changes in CIP deviations and changes in absolute values of CIP deviations. For the explanatory variable, information-robust monetary policy shock (Miranda-Agrippino and Ricco, 2021) and monetary policy shock robust to Fed response to news channel (Bauer and Swanson, 2023a) are considered.

B.1 Dependent Variable: Two-Day Change in CIP Deviations

First, I change measurements of $\Delta cid_{j,h,t}$ from one-day difference to two-day difference $cid_{j,h,t+1} - cid_{j,h,t-1}$ considering time-zone differences.

Table A.6 displays estimation results of regressing newly defined series of $\Delta cid_{j,h,t}$ on Δmp_t . Similar to the baseline estimation in Table 2, a contractionary US monetary policy shock declines CIP deviations with larger effects on short-term bases. The effect on 3-month basis is smaller than the baseline result while effects on longer-term bases are larger and significant. Also, *Path* factor leads to a rise in 3-month CIP deviation, which is at odds with the baseline result. For the most part, we can see that empirical results are robust to changing the dependent variable to a two-day difference in CIP deviations.

B.2 Dependent Variable: Change in Absolute Value of CIP Deviations

Since CIP deviations can take positive values, a decline in CIP deviations is not always equivalent to widening CIP deviations. A widening of CIP deviations is by definition larger size of CIP deviations, which can be measured by taking the absolute value of CIP deviations. Hence, in order to look at widening (or narrowing) more directly, I consider changes in absolute value of CIP deviations $\Delta |cid_{j,h,t}|$ as the dependent variable.

Then, I run the following regression:

$$\Delta |cid_{j,h,t}| = \alpha_j + \beta_h \Delta mp_t + \epsilon_{j,h,t}$$

CIP deviations widen in response to a contractionary US monetary policy shock if $\beta_h > 0$. In Table A.7, we can see that β_h of *NS* and *Target* are estimated to be significantly positive though the size of estimates is smaller than baseline results.

B.3 Information-Robust Monetary Policy Shock

I also show that the baseline estimation results are robust to the information effect of monetary policy. As in Miranda-Agrippino and Ricco (2021), there are two sources of the information effect:

Table A.6: Effects of US Monetary Policy Shock on CIP deviations

Note. This table presents the regression results of CIP deviations on 1pp contractionary US monetary policy shock for each maturity of 3-month, 1-year, 2-year, 3-year, 5-year, 7-year, and 10-year. For each maturity, there are two columns: the left column is the estimation result when *NS* is used as the US monetary policy shock whereas the right column is the one when *Target* and *Path* are used as proxies for the shock. Units of the estimates are in basis points. Driscoll-Kraay standard errors are reported in the parentheses unless the cross-sectional dependence is weak. If the cross-sectional dependence is weak, standard errors clustered at the currency level are reported instead. *N* denotes the number of observations of the regression respectively. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

the signaling channel and the slow absorption of information. First, monetary policy can signal fundamentals on which the policy rate is based to private decision makers (see [Romer and Romer, 2000](#); [Nakamura and Steinsson, 2018](#) for example). This signaling channel comes from the asymmetric information between the central bank and the market. Observing the policy rate which works as the signal, the private sector extract information on the fundamentals that the central bank may have more information on. For example, if the policy rate rises, then the private sector (households or firms for instance) may think that the economy is stronger than they expect. Then, a high-frequency surprise may not be shock; instead, it can reflect the revision of private sector's expectation on fundamentals. Second, [Coibion and Gorodnichenko \(2015\)](#) show that expectations respond gradually, rather than instantaneously, to fundamental shocks. This implies that fundamental shocks may not be instantaneously reflected to market prices, even prices in financial markets. In this case, high-frequency surprises may contain information on past fundamental shocks to which an exogenous shock should be orthogonal. In these two cases, Δmp may not be an exogenous "shock", confounding the estimation for β_h . In order to produce estimates robust to the information effect, information-robust

Note. This table presents the regression results of size of CIP deviations on 1pp contractionary US monetary policy shock for each maturity of 3-month, 1-year, 2-year, 3-year, 5-year, 7-year, and 10-year. For each maturity, there are two columns: the left column is the estimation result when *NS* is used as the US monetary policy shock whereas the right column is the one when *Target* and *Path* are used as proxies for the shock. Units of the estimates are in basis points. Driscoll-Kraay standard errors are reported in the parentheses unless the cross-sectional dependence is weak. If the cross-sectional dependence is weak, standard errors clustered at the currency level are reported instead. *N* denotes the number of observations of the regression respectively. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

monetary policy shocks are constructed and used as the proxy for the monetary policy shock.

As the first step, I test for the signalling channel of the US monetary policy following [Miranda-Agrippino and Ricco \(2021\)](#). They use Greenbook forecasts as proxies for the Fed's private information since the forecasts contain information on fundamentals for determining the monetary policy but are not open to the public. The forecasts are made for GDP growth rate, inflation, and unemployment rate which determine the systematic part of the monetary policy. These forecasts are published with 5 years of lag, implying that they are the private information of the Fed. In order to control for the Fed's private information, three monetary policy indicators (*NS*, *Target*, and *Path*) are projected on Greenbook forecasts as

$$\Delta mp_t = \alpha + \sum_{i=-1}^2 \beta'_i x_{t,i}^f + \sum_{i=-1}^2 \gamma'_i (x_{t,i}^f - x_{t-1,i}^f) + \Delta \widetilde{mp}_t \quad (\text{B.1})$$

where $x_{t,i}^f$ is the vector of Greenbook forecasts for GDP growth rate, inflation, and unemployment

rate. Subscript t is the date of FOMC announcement while subscript i is the forecast horizon: -1 for previous quarter, 0 for current quarter, 1 and 2 for next one and two quarters.⁴⁰ For the case of unemployment rate, only contemporaneous forecast is included as in [Romer and Romer \(2004\)](#) due to the multicollinearity. We also have the first-difference term $x_{t,i}^f - x_{t-1,i}^f$ which is the difference between forecasts published in current meeting and previous meeting.

The results of (B.1) are reported in Table A.8. Columns with *NS*, *Target*, and *Path* refer to the regression results when each monetary policy indicator is used as the dependent variable. Rows are Greenbook forecasts for fundamentals and their first difference from the previously published forecast. Estimates are roughly in line with the ones in [Romer and Romer \(2004\)](#), with the R^2 of 0.13 - 0.22 in this paper compared to 0.28 in [Romer and Romer \(2004\)](#). Also, the p-values of F-statistics from the regressions for *NS* and *Path* are below 0.001, implying that we can reject the null hypothesis that there is no signaling channel. The regression for *Target* has the p-value of 0.569, so the signaling channel does not exist for the target factor. Nevertheless, information-robust *Target* will be used in order to compare the information-robust shock with the baseline shock.

In the next step, we take the residual term $\Delta\widetilde{mp}$ from (B.1). $\Delta\widetilde{mp}$ is robust to the signalling effect since it is orthogonal to the Fed's information set. Controlling the Fed's information set, we can extract components from surprises in the interest rate futures that are orthogonal to the signalling channel. However, $\Delta\widetilde{mp}$ may still be subject to the imperfect information problem which brings about the slow absorption of information.

In order to resolve the imperfect information, I run the following AR(1) regression on $\Delta\widetilde{mp}$ and take the autoregressive part away:

$$\Delta\widetilde{mp}_t = \alpha_0 + \alpha_1\Delta\widetilde{mp}_{t-1} + \Delta mpi_t$$

By removing the serially correlated part in futures surprises, we can obtain the residual Δmpi_t for each series of *NS*, *Target*, and *Path*. This Δmpi_t is used as the information-robust monetary policy shock to estimate the robust effect of US monetary policy shock on CIP deviations:

$$\Delta cid_{j,h,t} = \alpha_j + \beta_h \Delta mpi_t + \epsilon_{j,h,t} \quad (\text{B.2})$$

Table A.9 shows the information-robust effect of the US monetary policy shock on CIP deviations for pre-GFC and post-GFC periods. Similar to the results in Table 2, effects of monetary policy are on short-term basis are large and significant for post-GFC periods. Broadly speaking, estimating information-robust effect does not produce qualitatively different estimates, which implies that the potential information effects may not be crucial problems in this analysis. Information-robust effects

⁴⁰Greenbook forecasts are made 6 days before the FOMC meeting, but they are not open to the public, so it is still private information at the time of the FOMC meeting.

Note. This table presents the regression results of high-frequency identified monetary policy shocks on Greenbook forecasts for GDP growth rate, inflation, and unemployment rate. For GDP growth rate and inflation, forecast horizons of -1 (previous quarter), 0 (current quarter), 1 (next quarter), and 2 (two quarters ahead) are included. For the case of unemployment rate, only contemporaneous forecast is included. Changes in forecasts for GDP growth rate and inflation from previous Greenbook are also included. Three columns *NS*, *Target*, and *Path* indicate regression results when each monetary policy indicator is used as the dependent variable. Heteroscedasticity-robust standard errors are reported in the parentheses. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

are larger for 3-month maturity while they are more muted for other maturities.

B.4 Monetary Policy Shock Robust to the Fed Response to News Channel

According to [Bauer and Swanson \(2023b\)](#), there is another concern on the exogeneity of high-frequency identified monetary policy shock: Fed response to news channel. This arises due to imperfect information on the Fed's monetary policy rule, resulting in correlation between high-frequency identified surprises and macroeconomic and financial data available before FOMC announcements. [Bauer and Swanson \(2023b\)](#) tackles this endogeneity by orthogonalizing high-frequency identified shocks with respect to macroeconomic and financial data:

$$\Delta mp_t = \alpha + \gamma' X_t + \Delta mpn_t$$

Table A.9: Effect of Information-robust US Monetary Policy Shock on CIP deviations

N	873	873	879	879	866	866		

Note. This table presents the regression results of CIP deviations on 1pp contractionary information-robust US monetary policy shock for each maturity of 3-month, 1-year, 2-year, 3-year, 5-year, 7-year, and 10-year. For each maturity, there are two columns: the left column is the estimation result when *NS* is used as the US monetary policy shock whereas the right column is the one when *Target* and *Path* are used as proxies for the shock. Units of the estimates are in basis points. Driscoll-Kraay standard errors are reported in the parentheses unless the cross-sectional dependence is weak. If the cross-sectional dependence is weak, standard errors clustered at the currency level are reported instead. *N* denotes the number of observations of the regression respectively. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Here, X_t is a vector of macroeconomic and financial data while Δmpn_t is the orthogonalized high-frequency identified shock which is robust to the Fed Response to news channel.

Table A.10 presents estimation results when the explanatory variable is Δmpn_t . Series of Δmpn_t are obtained from Bauer and Swanson (2023a). Note that they provide only Nakamura-Steinsson type monetary policy shocks robust to Fed response to news channel, so Table A.10 does not have estimates for *Target* and *Path* factors. Similar to the results in Bauer and Swanson (2023a) regarding financial variables, estimates remain largely unchanged, confirming that the baseline estimation is also robust to Fed response to news channel.

Units of the estimates are in basis points. Driscoll-Kraay standard errors are reported in the parentheses unless the cross-sectional dependence is weak. If the cross-sectional dependence is weak, standard errors clustered at the currency level are reported instead. N denotes the number of observations of the regression respectively. * $p < 0.10$, ** $p < 0.05$, *** $p < 0.01$

Appendix C Proof: Value Function Is Linear in Net Worth

In this section, I prove that the value function of US bank i is linear in its net worth, *i.e.* $V_{i,t} = \nu_t N_{i,t}$ by guess and verify method (see Section 3.2.6). First, let us guess $V_{i,t} = \nu_t N_{i,t}$. Note that ν_t is assumed to be common across all banks. Then, the optimization problem becomes

$$\begin{aligned} \nu_t = \max_{\phi_{H,i,t}, \phi_{X,i,t}} & E_t \left[\Omega_{t,t+1} \left\{ (R_{K,t+1} - R_t) \phi_{H,i,t} + \left(R_t^* \frac{S_t}{F_t} - R_t \right) \phi_{X,i,t} + R_t \right\} \right] \\ \text{s.t. } & \nu_t \geq \left[\left(\theta_{H1} + \theta_{H2} \frac{Q_t K_{H,t}}{P_t} \right) \phi_{H,i,t} + \left(\theta_{X1} + \theta_{X2} \frac{X_t}{P_t} \right) \phi_{X,i,t} \right] \end{aligned}$$

for the stochastic discount factor of bank $\Omega_{t,t+1}$ defined as

$$\Omega_{t,t+1} \equiv \Lambda_{t,t+1} (1 - \sigma + \sigma \nu_{t+1}) \quad (\text{C.1})$$

Banks' SDF is equivalent to the SDF of the representative household augmented by the expected value from bank's net worth $1 - \sigma + \sigma \nu_{t+1}$. When the bank exits with probability $1 - \sigma$, then one unit of net worth just transfers one unit to the households. If it stays with probability σ on the other hand, ν_{t+1} is created per unit of net worth. When ν_{t+1} is different from one, which happens in the existence of binding leverage constraint, the SDF of banks becomes different from that of households. Intuitively, the expected marginal value of net worth conditional on continuing business is equal to one if the leverage constraint does not bind and thus one unit of net worth does not produce any additional value. Conversely, if the leverage constraint binds, then marginal net worth loosens the leverage constraint and provides additional value, creating wedge between the SDF of households and the SDF of banks.

Defining the expected discounted returns on assets and net worth as

$$\nu_{H,t} \equiv E_t [\Omega_{t,t+1} (R_{K,t+1} - R_t)] \quad (\text{C.2})$$

$$\nu_{X,t} \equiv E_t [\Omega_{t,t+1} \left(R_t^* \frac{S_t}{F_t} - R_t \right)] \quad (\text{C.3})$$

$$\nu_{N,t} \equiv E_t [\Omega_{t,t+1}] R_t \quad (\text{C.4})$$

the Bellman equation becomes

$$\begin{aligned} \nu_t = \max_{\phi_{H,i,t}, \phi_{X,i,t}} & \nu_{H,t} \phi_{H,i,t} + \nu_{X,t} \phi_{X,i,t} + \nu_{N,t} \\ \text{s.t. } & \nu_t \geq \left[\left(\theta_{H1} + \theta_{H2} \frac{Q_t K_{H,t}}{P_t} \right) \phi_{H,i,t} + \left(\theta_{X1} + \theta_{X2} \frac{X_t}{P_t} \right) \phi_{X,i,t} \right] \end{aligned}$$

Then, we can obtain the first-order conditions as

$$\nu_{H,t} = \mu_t \left(\theta_{H1} + \theta_{H2} \frac{Q_t K_{H,t}}{P_t} \right) \quad (\text{C.5})$$

$$\nu_{X,t} = \mu_t \left(\theta_{X1} + \theta_{X2} \frac{X_t}{P_t} \right) \quad (\text{C.6})$$

for the Lagrangian multiplier μ_t of the leverage constraint.

Plugging the first-order conditions (C.5) and (C.6) into the leverage constraint and combining with the value function, we can obtain the franchise value per unit of net worth as

$$\nu_t = \frac{\nu_{N,t}}{1 - \mu_t} \quad (\text{C.7})$$

Since ν_t is the same for all banks and thus it does not depend on an individual bank's net worth, we can verify that $V_{i,t} = \nu_t N_{i,t}$.

Lastly, we aggregate variables across all banks for each period. Let us define the aggregate net worth, US government bond holding, and synthetic dollar funding as

$$\begin{aligned} N_t &\equiv \int_0^1 N_{i,t} di \\ K_{H,t} &\equiv \int_0^1 K_{H,i,t} di \\ X_t &\equiv \int_0^1 X_{i,t} di \end{aligned}$$

Since bank i 's optimization problem does not depend on its net worth due to the linearity of the value function, $\phi_{H,i,t}$ and $\phi_{X,i,t}$ are identical for all banks. Then,

$$\phi_{H,t} = \frac{Q_t K_{H,t}}{N_t} \quad (\text{C.8})$$

$$\phi_{X,t} = \frac{X_t}{N_t} \quad (\text{C.9})$$

Aggregating the leverage constraint (3.21) over all banks, we can obtain the relationship between leverage ratios and the franchise value as

$$\nu_t = \frac{1}{\mu_t} (\nu_{H,t} \phi_{H,t} + \nu_{X,t} \phi_{X,t}) \quad (\text{C.10})$$

The proof for non-US banks are the same. From (3.37), (3.38), (3.39), and (3.32),

$$\nu_t^* = \frac{\nu_{N,t}^*}{1 - \mu_t^*} \quad (\text{C.11})$$

This implies that ν_t^* is the same for all banks and thus the conjecture that $V_{i,t}^* = \nu_t^* N_{i,t}^*$ is verified.

Let us aggregate asset holdings and net worth across all banks as

$$\begin{aligned} N_t^* &\equiv \int_0^1 N_{i,t}^* di \\ K_{F,t}^* &\equiv \int_0^1 K_{F,i,t}^* di \\ K_{H,t}^* &\equiv \int_0^1 K_{H,i,t}^* di \end{aligned}$$

Since $\phi_{F,i,t}^*$, $\phi_{H,i,t}^*$, and $x_{i,t}^*$ are identical for all banks,

$$\phi_{F,t}^* = \frac{Q_t^* K_{F,t}^*}{N_t^*} \tag{C.12}$$

$$\phi_{H,t}^* = \frac{S_t Q_t^* K_{H,t}^*}{N_t^*} \tag{C.13}$$

$$\nu_t^* = \frac{1}{\mu_t^*} (\nu_{F,t}^* \phi_{F,t}^* + \nu_{H,t}^* (1 - x_t^*) \phi_{H,t}^* + \nu_{X,t}^* x_t^* \phi_{H,t}^*) \tag{C.14}$$

Appendix D Additional Blocks of the Model

In this section, we describe sectors of the non-US economy other than financial intermediaries: households, capital good producers, consumption and investment good retailers, wholesalers, firms, and the government. In addition, we specify market clearing conditions except the FX swap market and the balance of payment equation.

D.1 Non-US Household

Preference of non-US households is represented by the following CRRA utility function

$$E_0 \sum_{t=0}^{\infty} \beta^t \left[\frac{C_t^{*1-\gamma} - 1}{1-\gamma} - \kappa^* \frac{L_t^{*1+\varphi}}{1+\varphi} \right]$$

where C_t^* is the aggregate consumption and L_t^* is the labor supply of the non-US. The elasticity of intertemporal substitution and the Frisch elasticity are all set to be the same as the home country while the disutility of labor κ^* is allowed to be different from the US.

For each period, the household can consume C_t^* or deposit D_t^* to financial intermediaries. Gross return rate of deposits from period t to $t+1$ is denoted as R_t^* . Therefore, the sequential budget constraint of the household is given by

$$P_t^* C_t^* + D_t^* = W_t^* L_t^* + R_{t-1}^* D_{t-1}^* + \Pi_t^* + TR_t^* \quad (\text{D.1})$$

where Π_t^* is the net profit that the household obtains from all firms including financial intermediaries while TR_t^* is the net transfer from the government. Then, the optimality conditions from the household's optimization problem are

$$\kappa^* C_t^{*\gamma} L_t^{*\varphi} = \frac{W_t^*}{P_t^*} \quad (\text{D.2})$$

$$E_t [\Lambda_{t,t+1}^*] R_t^* = 1 \quad (\text{D.3})$$

for the SDF of the household defined as

$$\Lambda_{t,t+1}^* \equiv \beta \left(\frac{C_{t+1}^*}{C_t^*} \right)^{-\gamma} \left(\frac{P_t^*}{P_{t+1}^*} \right) \quad (\text{D.4})$$

D.2 Non-US Capital Good Producers

Similar to the US, there are perfectly competitive capital good producers purchasing aggregate investment goods at P_t^* and selling at Q_t^* . The aggregate capital evolves following the law of motion

$$K_t^* = I_t^* + (1 - \delta)K_{t-1}^* \quad (\text{D.5})$$

Since the per-period profit of capital good producer is given by

$$\Pi_t^{K^*} \equiv Q_t^* I_t^* - P_t^* I_t^* \left(1 + \frac{\psi_I}{2} \left(\frac{I_t^*}{I_{t-1}^*} - 1 \right)^2 \right)$$

we can get the optimality condition as

$$Q_t^* = P_t^* \left[1 + \frac{\psi_I}{2} \left(\frac{I_t^*}{I_{t-1}^*} - 1 \right)^2 + \psi_I \frac{I_t^*}{I_{t-1}^*} \left(\frac{I_t^*}{I_{t-1}^*} - 1 \right) \right] - E_t \left[\Lambda_{t,t+1}^* P_{t+1}^* \psi_I \left(\frac{I_{t+1}^*}{I_t^*} \right)^2 \left(\frac{I_{t+1}^*}{I_t^*} - 1 \right) \right] \quad (\text{D.6})$$

D.3 Non-US Retailers

Domestically-produced consumption good $C_{F,t}^*$ and imported consumption good $C_{H,t}^*$ are aggregated into C_t^* by perfectly competitive consumption good retailers whose aggregation technology is described as the following CES function:

$$C_t^* \equiv \left[\omega^{\frac{1}{\nu}} C_{F,t}^{*\frac{\nu-1}{\nu}} + (1 - \omega)^{\frac{1}{\nu}} C_{H,t}^{*\frac{\nu-1}{\nu}} \right]^{\frac{\nu}{\nu-1}}$$

Here, the home-bias parameter ω and the elasticity of substitution between domestically-produced and imported goods are set at the same value as the US. Then, the following demand functions are obtained from the profit maximization problem of consumption good retailers

$$C_{F,t}^* = \omega \left(\frac{P_{F,t}^*}{P_t^*} \right)^{-\nu} C_t^* \quad (\text{D.7})$$

$$C_{H,t}^* = (1 - \omega) \left(\frac{P_{H,t}^*}{P_t^*} \right)^{-\nu} C_t^* \quad (\text{D.8})$$

where $P_{F,t}^*$ and $P_{H,t}^*$ are non-US prices of goods produced in the non-US and in the US respectively. Also, the aggregate price index P_t^* is given by

$$P_t^* = \left[\omega P_{F,t}^{*1-\nu} + (1 - \omega) P_{H,t}^{*1-\nu} \right]^{\frac{1}{1-\nu}}$$

Let us define the non-US' terms-of-trade T_t^* as $P_{F,t}^*/P_{H,t}^*$. Note that $T_t^* = T_t$ under the law of one price, but it does not hold generally under the LCP. Then,

$$P_{H,t}^* = P_t^* [\omega T_t^{*1-\nu} + 1 - \omega]^{-\frac{1}{1-\nu}} \quad (\text{D.9})$$

$$P_{F,t}^* = P_t^* [\omega + (1 - \omega) T_t^{*-(1-\nu)}]^{-\frac{1}{1-\nu}} \quad (\text{D.10})$$

Similarly, perfectly competitive investment goods retailers aggregate domestically produced investment goods $I_{F,t}^*$ (produced in the non-US) and imported investment goods $I_{H,t}^*$ (produced in the US) into I_t^* by the following CES aggregator:

$$I_t^* \left(1 + \frac{\psi_I}{2} \left(\frac{I_t^*}{I_{t-1}^*} - 1 \right)^2 \right) \equiv [\omega^{\frac{1}{\nu}} I_{F,t}^{*\frac{\nu-1}{\nu}} + (1 - \omega)^{\frac{1}{\nu}} I_{H,t}^{*\frac{\nu-1}{\nu}}]^{-\frac{\nu}{\nu-1}}$$

Then, we can obtain the following demand functions:

$$I_{F,t}^* = \omega \left(\frac{P_{F,t}^*}{P_t^*} \right)^{-\nu} I_t^* \left(1 + \frac{\psi_I}{2} \left(\frac{I_t^*}{I_{t-1}^*} - 1 \right)^2 \right) \quad (\text{D.11})$$

$$I_{H,t}^* = (1 - \omega) \left(\frac{P_{H,t}^*}{P_t^*} \right)^{-\nu} I_t^* \left(1 + \frac{\psi_I}{2} \left(\frac{I_t^*}{I_{t-1}^*} - 1 \right)^2 \right) \quad (\text{D.12})$$

D.4 Non-US Wholesalers

Similar to the US, there are perfectly competitive wholesalers with aggregation technology given by

$$Y_{F,t}^* \equiv \left[\int_0^1 Y_{F,t}^*(j)^{\frac{\epsilon-1}{\epsilon}} dj \right]^{\frac{\epsilon}{\epsilon-1}}$$

$$Y_{F,t} \equiv \left[\int_0^1 Y_{F,t}(j)^{\frac{\epsilon-1}{\epsilon}} dj \right]^{\frac{\epsilon}{\epsilon-1}}$$

Let us denote the price of $Y_{F,t}^*(j)$ and $Y_{F,t}(j)$ as $P_{F,t}^*(j)$ and $P_{F,t}(j)$ respectively. Then, the demand functions for domestically-spent and exported varieties are

$$Y_{F,t}^*(j) = \left(\frac{P_{F,t}^*(j)}{P_{F,t}^*} \right)^{-\epsilon} Y_{F,t}^* \quad (\text{D.13})$$

$$Y_{F,t}(j) = \left(\frac{P_{F,t}(j)}{P_{F,t}} \right)^{-\epsilon} Y_{F,t} \quad (\text{D.14})$$

D.5 Non-US Firm

Each variety $j \in [0, 1]$ in the non-US is also produced by the following production function

$$Y_t^*(j) = Z_t^* I_t^*(j)^{1-\alpha} K_{t-1}^*(j)^\alpha$$

where Z_t^* is assumed to be a constant value of one.

From the cost minimization of firm j , we can obtain the following demand functions for labor and capital

$$W_t^* = (1 - \alpha)MC_t^* \frac{Y_t^*(j)}{L_t^*(j)} \quad (\text{D.15})$$

$$\tilde{R}_{K,t}^* = \alpha MC_t^* \frac{Y_t^*(j)}{K_{t-1}^*(j)} \quad (\text{D.16})$$

for the marginal cost MC_t^* given by

$$MC_t^* = \frac{1}{Z_t^*} \frac{W_t^{*1-\alpha} \tilde{R}_{K,t}^{*\alpha}}{(1 - \alpha)^{1-\alpha} \alpha^\alpha} \quad (\text{D.17})$$

According to the assumption of LCP, firm j chooses $P_{F,t}^*(j)$ and $P_{F,t}(j)$ separately for its varieties sold in the non-US and in the US. Let us assume that the firm is subject to the same price adjustment cost ψ_P as the US. Then, firm j 's periodic profit $\Pi_t^{P*}(j)$ is

$$\begin{aligned} \Pi_t^{P*}(j) = & (1 + s^*) (P_{F,t}^*(j) Y_{F,t}^*(j) + S_t P_{F,t}(j) Y_{F,t}(j)) - TC_t^*(j) \\ & - \frac{\psi_P}{2} \left[\left(\frac{P_{F,t}^*(j)}{P_{F,t-1}^*(j)} - 1 \right)^2 P_{F,t}^* Y_{F,t}^* + \left(\frac{P_{F,t}(j)}{P_{F,t-1}(j)} - 1 \right)^2 S_t P_{F,t} Y_{F,t} \right] \end{aligned}$$

From (D.13) and (D.14), firm j 's life-time profit maximization problem defined as

$$\max_{\{P_{F,t+s}^*(j), P_{F,t+s}(j)\}_{s=0}^\infty} E_t \sum_{s=0}^\infty \Lambda_{t,t+s}^* \Pi_{t+s}^{P*}(j)$$

yields the following first-order conditions:

$$\begin{aligned} (1 + s^*)(\epsilon - 1) = & \epsilon \frac{MC_t^*}{P_{F,t}^*} - \psi_P \left(\frac{P_{F,t}^*}{P_{F,t-1}^*} - 1 \right) \frac{P_{F,t}^*}{P_{F,t-1}^*} \\ & + E_t \left[\Lambda_{t,t+1}^* \psi_P \left(\frac{P_{F,t+1}^*}{P_{F,t}^*} - 1 \right) \left(\frac{P_{F,t+1}^*}{P_{F,t}^*} \right)^2 \frac{Y_{F,t+1}^*}{Y_{F,t}^*} \right] \end{aligned} \quad (\text{D.18})$$

$$\begin{aligned} (1 + s^*)(\epsilon - 1) = & \epsilon \frac{MC_t^*}{S_t P_{F,t}} - \psi_P \left(\frac{P_{F,t}}{P_{F,t-1}} - 1 \right) \frac{P_{F,t}}{P_{F,t-1}} \\ & + E_t \left[\Lambda_{t,t+1}^* \psi_P \left(\frac{P_{F,t+1}}{P_{F,t}} - 1 \right) \left(\frac{P_{F,t+1}}{P_{F,t}} \right)^2 \frac{S_{t+1}}{S_t} \frac{Y_{F,t+1}}{Y_{F,t}} \right] \end{aligned} \quad (\text{D.19})$$

D.6 Non-US Monetary Policy

Monetary policy of the EU is

$$\frac{R_t^*}{R^*} = \left(\frac{R_{t-1}^*}{R^*} \right)^{\rho_R} \left(\frac{P_t^*}{P_{t-1}^*} \right)^{\phi_\pi(1-\rho_R)} \epsilon_{R,t}^* \quad (\text{D.20})$$

where

$$\log \epsilon_{R,t}^* = \rho_m^* \log \epsilon_{R,t-1}^* + \sigma_m^* \epsilon_{m,t}^* \quad (\text{D.21})$$

for the EU monetary policy shock $\epsilon_{m,t}^* \sim N(0, 1)$.

D.7 Non-US Fiscal Policy

As the US, the fiscal policy of the EU is

$$TR_t^* + s^* P_{F,t}^* (Y_{F,t}^* + Y_{F,t}) = 0 \quad (\text{D.22})$$

D.8 Equilibrium

Let us define the real exchange rate $\mathcal{E}_t$ as

$$\mathcal{E}_t \equiv \frac{S_t P_t}{P_t^*}$$

Then, it can be expressed as a function of terms-of-trade as

$$\mathcal{E}_t = \frac{S_t P_{H,t}}{P_{H,t}^*} \left[\frac{\omega + (1 - \omega) T_t^{1-\nu}}{\omega T_t^{*1-\nu} + 1 - \omega} \right]^{\frac{1}{1-\nu}}$$

for $T_t^* = P_{F,t}^* / P_{H,t}^*$. Let us define deviations from the law of one price for the US and the non-US goods as

$$\begin{aligned} \mathcal{E}_t^H &\equiv \frac{S_t P_{H,t}}{P_{H,t}^*} \\ \mathcal{E}_t^F &\equiv \frac{S_t P_{F,t}}{P_{F,t}^*} \end{aligned}$$

Note that $\mathcal{E}_t^H = \mathcal{E}_t^F = 1$ under the law of one price. From the above definitions,

$$\mathcal{E}_t = \mathcal{E}_t^H \left[\frac{\omega + (1 - \omega)T_t^{1-\nu}}{\omega T_t^{*1-\nu} + 1 - \omega} \right]^{\frac{1}{1-\nu}} \quad (\text{D.23})$$

$$\mathcal{E}_t^F = \mathcal{E}_t^H \frac{T_t}{T_t^*} \quad (\text{D.24})$$

Meanwhile, the market clearing conditions for the US and the non-US capital are

$$K_t = K_{H,t} + K_{H,t}^* \quad (\text{D.25})$$

$$K_t^* = K_{F,t}^* \quad (\text{D.26})$$

From the market clearing condition for US goods sold domestically and exported, we can obtain the following resource constraint for $Y_{H,t}$ and $Y_{H,t}^*$ as

$$Y_{H,t} = C_{H,t} + I_{H,t} + \frac{\psi_P}{2} \left(\frac{P_{H,t}}{P_{H,t-1}} - 1 \right)^2 Y_{H,t}$$

$$Y_{H,t}^* = C_{H,t}^* + I_{H,t}^* + \frac{\psi_P}{2} \left(\frac{P_{H,t}^*}{P_{H,t-1}^*} - 1 \right)^2 Y_{H,t}^*$$

Combining with (3.7),

$$\left[1 - \frac{\psi_P}{2} \left(\frac{P_{H,t}}{P_{H,t-1}} - 1 \right)^2 \right] Y_{H,t} = \omega \left(\frac{P_{H,t}}{P_t} \right)^{-\nu} \left[C_t + I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1 \right)^2 \right) \right] \quad (\text{D.27})$$

$$\left[1 - \frac{\psi_P}{2} \left(\frac{P_{H,t}^*}{P_{H,t-1}^*} - 1 \right)^2 \right] Y_{H,t}^* = (1 - \omega) \left(\frac{P_{H,t}^*}{P_t^*} \right)^{-\nu} \left[C_t^* + I_t^* \left(1 + \frac{\psi_I}{2} \left(\frac{I_t^*}{I_{t-1}^*} - 1 \right)^2 \right) \right] \quad (\text{D.28})$$

while the total output Y_t is the sum of $Y_{H,t}$ and $Y_{H,t}^*$ as

$$Y_t = Y_{H,t} + Y_{H,t}^* \quad (\text{D.29})$$

Similarly, the market clearing conditions for EU goods can be obtained as

$$\left[1 - \frac{\psi_P}{2} \left(\frac{P_{F,t}^*}{P_{F,t-1}^*} - 1 \right)^2 \right] Y_{F,t}^* = \omega \left(\frac{P_{F,t}^*}{P_t^*} \right)^{-\nu} \left[C_t^* + I_t^* \left(1 + \frac{\psi_I}{2} \left(\frac{I_t^*}{I_{t-1}^*} - 1 \right)^2 \right) \right] \quad (\text{D.30})$$

$$\left[1 - \frac{\psi_P}{2} \left(\frac{P_{F,t}}{P_{F,t-1}} - 1 \right)^2 \right] Y_{F,t} = (1 - \omega) \left(\frac{P_{F,t}}{P_t} \right)^{-\nu} \left[C_t + I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1 \right)^2 \right) \right] \quad (\text{D.31})$$

$$Y_t^* = Y_{F,t}^* + Y_{F,t} \quad (\text{D.32})$$

Appendix E Equilibrium Equations

The competitive equilibrium $\{\Lambda_{t,t+1}, \Lambda_{t,t+1}^*, R_t, R_t^*, R_{K,t}, R_{K,t}^*, \mathcal{E}_t, \mathcal{E}_t^H, \mathcal{E}_t^F, f_t, L_t, L_t^*, C_t, C_t^*, \Pi_t, \Pi_t^*, \Pi_t^S, p_{H,t}, p_{H,t}^*, p_{F,t}, p_{F,t}^*, T_t, T_t^*, \Omega_{t,t+1}, \Omega_{t,t+1}^*, n_t, n_t^*, x_t, \phi_{H,t}, \phi_{X,t}, \phi_{F,t}^*, \phi_{H,t}^*, \nu_{H,t}, \nu_{X,t}, \nu_{N,t}, \nu_t, \mu_t, \nu_{F,t}^*, \nu_{H,t}^*, \nu_{X,t}^*, \nu_{N,t}^*, \nu_t^*, \mu_t^*, K_t, K_t^*, K_{H,t}, K_{F,t}^*, K_{H,t}^*, x_t, tr_t, tr_t^*, Y_t, Y_t^*, Y_{H,t}, Y_{H,t}^*, Y_{F,t}, Y_{F,t}^*, w_t, w_t^*, \tilde{r}_{K,t}, \tilde{r}_{K,t}^*, mc_t, mc_t^*, I_t, I_t^*, q_t, q_t^*, \epsilon_{R,t}, \epsilon_{R,t}^*\}$ are determined by the following equations.

Here, we converted nominal variables into real variables as

$$\begin{aligned} \mathcal{E}_t &\equiv \frac{S_t P_t}{P_t^*} \quad , \quad f_t \equiv \frac{F_t P_t^*}{P_t} \\ \Pi_t &\equiv \frac{P_t}{P_{t-1}} \quad , \quad \Pi_t^* \equiv \frac{P_t^*}{P_{t-1}^*} \quad , \quad \Pi_t^S \equiv \frac{S_t}{S_{t-1}} \\ p_{H,t} &\equiv \frac{P_{H,t}}{P_t} \quad , \quad p_{F,t} \equiv \frac{P_{F,t}}{P_t} \\ p_{H,t}^* &\equiv \frac{P_{H,t}^*}{P_t^*} \quad , \quad p_{F,t}^* \equiv \frac{P_{F,t}^*}{P_t^*} \\ n_t &\equiv \frac{N_t}{P_t} \quad , \quad n_t^* \equiv \frac{N_t^*}{P_t^*} \\ x_t &\equiv \frac{X_t}{P_t} \quad , \quad q_t \equiv \frac{Q_t}{P_t} \quad , \quad q_t^* \equiv \frac{Q_t^*}{P_t^*} \\ w_t &\equiv \frac{W_t}{P_t} \quad , \quad w_t^* \equiv \frac{W_t^*}{P_t^*} \\ \tilde{r}_t &\equiv \frac{\tilde{R}_t}{P_t} \quad , \quad \tilde{r}_t^* \equiv \frac{\tilde{R}_t^*}{P_t^*} \\ mc_t &\equiv \frac{MC_t}{P_t} \quad , \quad mc_t^* \equiv \frac{MC_t^*}{P_t^*} \\ tr_t &\equiv \frac{TR_t}{P_t} \quad , \quad tr_t^* \equiv \frac{TR_t^*}{P_t^*} \end{aligned}$$

$$\kappa C_t^\gamma L_t^\varphi = w_t \quad (\text{E.1})$$

$$\mathcal{E}_t = \mathcal{E}_{t-1} \frac{\Pi_t^S \Pi_t}{\Pi_t^*} \quad (\text{E.67})$$

$$\log \epsilon_{R,t} = \rho_m \log \epsilon_{R,t-1} + \epsilon_{m,t} \quad (\text{E.68})$$

$$\log \epsilon_{R,t}^* = \rho_m \log \epsilon_{R,t-1}^* + \epsilon_{m,t}^* \quad (\text{E.69})$$

Appendix F Steady-states

Steady-state variables are denoted as the ones without time subscript. In the steady-state with zero inflation and depreciation rate, equilibrium equations are

$$\kappa C^\gamma L^\varphi = w \quad (\text{F.1})$$

$$\kappa^* C^{*\gamma} L^{*\varphi} = w^* \quad (\text{F.2})$$

$$\Lambda = \beta \quad (\text{F.3})$$

$$\mathcal{E} = \mathcal{E}_H \left[\frac{\omega + (1 - \omega)T^{1-\nu}}{\omega T^{*1-\nu} + 1 - \omega} \right]^{\frac{1}{1-\nu}} \quad (\text{F.4})$$

$$\mathcal{E}_F = \mathcal{E}_H \frac{T}{T^*} \quad (\text{F.5})$$

$$p_H = [\omega + (1 - \omega)T^{1-\nu}]^{-\frac{1}{1-\nu}} \quad (\text{F.6})$$

$$p_F = [\omega T^{-(1-\nu)} + 1 - \omega]^{-\frac{1}{1-\nu}} \quad (\text{F.7})$$

$$p_H^* = [\omega T^{*1-\nu} + 1 - \omega]^{-\frac{1}{1-\nu}} \quad (\text{F.8})$$

$$p_F^* = [\omega + (1 - \omega)T^{*-(1-\nu)}]^{-\frac{1}{1-\nu}} \quad (\text{F.9})$$

$$\Lambda^* = \beta \quad (\text{F.10})$$

$$\Lambda R = 1 \quad (\text{F.11})$$

$$\Lambda^* R^* = 1 \quad (\text{F.12})$$

$$R_K = \frac{\tilde{r}_K + (1 - \delta)q}{q} \quad (\text{F.13})$$

$$R_K^* = \frac{\tilde{r}_K^* + (1 - \delta)q^*}{q^*} \quad (\text{F.14})$$

$$\Omega = \Lambda(1 - \sigma + \sigma\nu) \quad (\text{F.15})$$

$$\Omega^* = \Lambda^*(1 - \sigma + \sigma\nu^*) \quad (\text{F.16})$$

$$\nu_H = \Omega(R_K - R) \quad (\text{F.17})$$

$$\nu_X = \Omega \left(R^* \frac{\mathcal{E}}{f} - R \right) \quad (\text{F.18})$$

$$\nu_N = \Omega R \quad (\text{F.19})$$

$$\nu_H = \mu(\theta_{H1} + \theta_{H2}qK_H) \quad (\text{F.20})$$

$$\nu_X = \mu(\theta_{X1} + \theta_{X2}x) \quad (\text{F.21})$$

$$\nu = \frac{\nu_N}{1 - \mu} \quad (\text{F.22})$$

$$\phi_H = \frac{qK_H}{n} \quad (\text{F.23})$$

$$\phi_X = \frac{x}{n} \quad (\text{F.24})$$

$$\nu = \frac{1}{\mu}(\nu_H\phi_H + \nu_X\phi_X) \quad (\text{F.25})$$

$$n = \sigma \left[(R_K - R)\phi_H + \left(R^* \frac{\mathcal{E}}{f} - R \right) \phi_X + R \right] n + (1 - \sigma)\xi(\phi_H + \phi_X)n \quad (\text{F.26})$$

$$\nu_F^* = \Omega^*(R_K^* - R^*) \quad (\text{F.27})$$

$$\nu_H^* = \Omega^*(R_K - R^*) \quad (\text{F.28})$$

$$\nu_X^* = \Omega^* \left(R_K - R^* \frac{\mathcal{E}}{f} \right) \quad (\text{F.29})$$

$$\nu_N^* = \Omega^* R^* \quad (\text{F.30})$$

$$\nu_F^* = \mu^*(\theta_{F1}^* + \theta_{F2}^* q^* K_F^*) \quad (\text{F.31})$$

$$\nu_H^* = \mu^*(\theta_{H1}^* + \theta_{H2}^*(1 - x^*)\mathcal{E}qK_H^*) \quad (\text{F.32})$$

$$\nu_X^* = \mu^*(\theta_{X1}^* + \theta_{X2}^* \mathcal{E}x^* \mathcal{E}qK_H^*) \quad (\text{F.33})$$

$$\nu^* = \frac{\nu_N^*}{1 - \mu^*} \quad (\text{F.34})$$

$$\phi_F^* = \frac{q^* K_F^*}{n^*} \quad (\text{F.35})$$

$$\phi_H^* = \frac{\mathcal{E}qK_H^*}{n^*} \quad (\text{F.36})$$

$$\nu^* = \frac{1}{\mu^*}(\nu_F^* \phi_F^* + \nu_H^*(1 - x^*)\phi_H^* + \nu_X^* x^* \phi_H^*) \quad (\text{F.37})$$

$$n^* = \sigma \left[(R_K^* - R^*)\phi_F^* + (R_K - R^*)(1 - x^*)\phi_H^* + \left(R_K - R^* \frac{\mathcal{E}}{f} \right) x^* \phi_H^* + R^* \right] n^* + (1 - \sigma)\xi(\phi_F^* + \phi_H^*)n^* \quad (\text{F.38})$$

$$I = \delta K \quad (\text{F.39})$$

$$I^* = \delta K^* \quad (\text{F.40})$$

$$q = 1 \quad (\text{F.41})$$

$$q^* = 1 \quad (\text{F.42})$$

$$w = (1 - \alpha)mc \frac{Y}{L} \quad (\text{F.43})$$

$$\tilde{r}_K = \alpha mc \frac{Y}{K} \quad (\text{F.44})$$

$$mc = \frac{w^{1-\alpha} \tilde{r}_K^\alpha}{(1 - \alpha)^{1-\alpha} \alpha^\alpha} \quad (\text{F.45})$$

$$w^* = (1 - \alpha)mc^* \frac{Y^*}{L^*} \quad (\text{F.46})$$

$$\tilde{r}_K^* = \alpha mc^* \frac{Y^*}{K^*} \quad (\text{F.47})$$

$$mc^* = \frac{w^{*1-\alpha} \tilde{r}_K^{*\alpha}}{(1 - \alpha)^{1-\alpha} \alpha^\alpha} \quad (\text{F.48})$$

$$R = \bar{R} \quad (\text{F.49})$$

$$R^* = \bar{R}^* \quad (\text{F.50})$$

$$tr + s \left(p_H Y_H + \frac{1}{\mathcal{E}} p_H^* Y_H^* \right) = 0 \quad (\text{F.51})$$

$$tr^* + s^* (p_F^* Y_F^* + \mathcal{E} p_F Y_F) = 0 \quad (\text{F.52})$$

$$(1 + s)(\epsilon - 1) = \epsilon \frac{mc}{p_H} \quad (\text{F.53})$$

$$(1 + s)(\epsilon - 1) = \epsilon \frac{\mathcal{E} mc}{p_H^*} \quad (\text{F.54})$$

$$(1 + s^*)(\epsilon - 1) = \epsilon \frac{mc^*}{p_F^*} \quad (\text{F.55})$$

$$(1 + s^*)(\epsilon - 1) = \epsilon \frac{mc^*}{\mathcal{E} p_F} \quad (\text{F.56})$$

$$Y_H = \omega p_H^{-\nu} (C + I) \quad (\text{F.57})$$

$$Y_H^* = (1 - \omega) p_H^{*- \nu} (C^* + I^*) \quad (\text{F.58})$$

$$Y = Y_H + Y_H^* \quad (\text{F.59})$$

$$Y_F^* = \omega p_F^{*- \nu} (C^* + I^*) \quad (\text{F.60})$$

$$Y_F = (1 - \omega) p_F^{-\nu} (C + I) \quad (\text{F.61})$$

$$Y^* = Y_F + Y_F^* \quad (\text{F.62})$$

$$x = x^* q K_H^* \quad (\text{F.63})$$

$$K = K_H + K_H^* \quad (\text{F.64})$$

$$K^* = K_F^* \quad (\text{F.65})$$

$$p_H Y_H + \frac{1}{\mathcal{E}} p_H^* Y_H^* - C - I + \left(R^* \frac{\mathcal{E}}{f} - 1 \right) x - (R_K - 1) q K_H^* = 0 \quad (\text{F.66})$$

First, discount factor β is calibrated as 0.99 to match yearly risk-free rate 4%. Then,

$$\Lambda = \Lambda^* = \beta$$

$$R = R^* = \frac{1}{\beta}$$

Steady-state labor L and L^* are assumed to be 1/3.

Next, in order to calibrate θ_{H1} , θ_{X1} , θ_{F1}^* , θ_{H1}^* , and θ_{X1}^* , we target the following five (yearly)

empirical moments:

- Excess return on US capital: 100bp
- Excess return on non-US capital: 100bp
- CIP deviation for post-GFC periods: -21bp
- Domestic investment share : 0.54
- US NFA-to-GDP ratio: -0.439

From the first two empirical moments,

$$\begin{aligned} R_K &= R + 0.01/4 \\ R_K^* &= R^* + 0.01/4 \end{aligned}$$

From the definition of gross return rate on capital (F.13) and (F.14)

$$\begin{aligned} \tilde{r}_K &= R_K - (1 - \delta) \\ \tilde{r}_K^* &= R_K^* - (1 - \delta) \end{aligned}$$

The steady-state CIP deviation pins down the forward premium $f/\mathcal{E} = R^*/(R + 0.0021/4)$.

Building on the above steady-state values, we solve for the steady-state terms-of-trade T . (F.6) - (F.9) show that price variables are functions of T . Also, the spot exchange rate $\mathcal{E}$ is expressed in terms of T in (F.4). Since the subsidy s and s^* are imposed to get rid of steady-state markup, $mc = p_H$ and $mc^* = p_F^*$, which are also functions of T . Then, from (F.43) - (F.45) and (F.46) - (F.48), we can derive K and K^* as functions of T :

$$\begin{aligned} K &= \left[\alpha \frac{L^{1-\alpha}}{\tilde{r}_K} mc \right]^{\frac{1}{1-\alpha}} \\ K^* &= \left[\alpha \frac{L^{*1-\alpha}}{\tilde{r}_K^*} mc^* \right]^{\frac{1}{1-\alpha}} \end{aligned}$$

This implies that Y and Y^* are also functions of T , and $I = \delta K$ and $I^* = \delta K^*$ can be expressed in terms of T . From the fourth empirical moment, the share of non-US banks' domestic capital holdings (in value) to the total capital holdings is

$$\frac{q^* K_F^*}{q^* K_F^* + \mathcal{E} q K_H^*} = 0.54$$

Since $q = q^* = 1$ and $K_F^* = K^*$,

$$K_H^* = \frac{1 - 0.54}{0.54} \frac{K^*}{\mathcal{E}}$$

Finally, since the US real NFA in this model is $x - qK_H^*$, the final bullet point of the five empirical moments implies

$$x = qK_F^* - 0.439 * 4 * p_H * Y$$

Then, the balance of payment equation (F.66) implies that C is also a function of T as

$$C = p_H Y - I + \left(R^* \frac{\mathcal{E}}{f} - 1 \right) x - (R_K - 1) q K_H^*$$

Combining (F.59) with resource constraints (F.57) and (F.58),

$$C^* = \frac{Y - \omega p_H^{-\nu} (C + I)}{(1 - \omega) p_H^{*- \nu}} - I^*$$

which is also a function of T . Then, T can be solved from

$$Y^* = \omega p_F^{*- \nu} (C^* + I^*) + (1 - \omega) p_F^{-\nu} (C + I)$$

since both the LHS and the RHS are functions of T .

Y_H , Y_H^* , Y_F^* , and Y_F are directly calculated from (F.57), (F.58), (F.60), and (F.61). The steady-state real forward exchange rate is

$$f = \frac{f}{\mathcal{E}} \cdot \mathcal{E}$$

Real wage w and w^* are obtained from (F.43) and (F.46) while κ and κ^* are calibrated as

$$\begin{aligned} \kappa &= \frac{w}{C^\gamma L^\varphi} \\ \kappa^* &= \frac{w^*}{C^{*\gamma} L^{*\varphi}} \end{aligned}$$

Regarding the government side, government transfers tr and tr^* are derived from (F.51) and (F.52) as

$$\begin{aligned} tr &= -s \cdot p_H (Y_H + Y_H^*) \\ tr^* &= -s^* \cdot p_F^* (Y_F^* + Y_F) \end{aligned}$$

σ is calibrated as 0.95 to match banks' expected operation horizon of 5 years. Let us target the aggregate leverage ratio of US and non-US bank of 6 to calibrate ξ . Then,

$$n = \frac{qK_H + x}{6}$$

$$n^* = \frac{q^*K_F^* + \mathcal{E}qK_H^*}{6}$$

We can then derive the steady-state ratio of each asset to net worth as

$$\phi_H = \frac{qK_H}{n}$$

$$\phi_X = \frac{x}{n}$$

$$\phi_F^* = \frac{q^*K_F^*}{n^*}$$

$$\phi_H^* = \frac{\mathcal{E}qK_H^*}{n^*}$$

From the law of motions for aggregate net worth (F.26) and (F.38),

$$\xi = \frac{1 - \sigma \left[(R_K - R) \phi_H + \left\{ R^* - \left(R + \frac{f}{\xi} - 1 \right) \right\} \phi_X + R \right]}{(1 - \sigma)(\phi_H + \phi_X)}$$

$$\xi^* = \frac{1 - \sigma \left[(R_K^* - R^*) \phi_F^* + (R_K - R^*)(1 - x^*) \phi_H^* + \left\{ R_K - \left(R^* + 1 - \frac{f}{\xi} \right) \right\} x^* \phi_H^* + R^* \right]}{(1 - \sigma)(\phi_F^* + \phi_H^*)}$$

(F.17), (F.18), and (F.19) imply that marginal values of K_H , x and net worth are functions of the US bank's SDF Ω . Plugging these into (F.19) and (F.25), we can obtain the steady-state μ as

$$\mu = \frac{(R_k - R) \phi_H + \left(R^* \frac{\mathcal{E}}{f} - R \right) \phi_X}{(R_k - R) \phi_H + \left(R^* \frac{\mathcal{E}}{f} - R \right) \phi_X + R}$$

Similarly, since (F.27), (F.28), (F.29) are functions of Ω^* , (F.34) and (F.37) yield

$$\mu^* = \frac{(R_k^* - R^*) \phi_F^* + (R_k - R^*)(1 - x^*) \phi_H^* + \left(R_k - R^* \frac{\mathcal{E}}{f} \right) x^* \phi_H^*}{(R_k^* - R^*) \phi_F^* + (R_k - R^*)(1 - x^*) \phi_H^* + \left(R_k - R^* \frac{\mathcal{E}}{f} \right) x^* \phi_H^* + R^*}$$

(F.15) and (F.16) suggest that Ω is a function of ν while Ω^* is a function of ν^* . From (F.26) and

(F.38),

$$\begin{aligned}\nu &= \frac{1 - \sigma}{1 - \sigma - \mu} \\ \nu^* &= \frac{1 - \sigma}{1 - \sigma - \mu^*}\end{aligned}$$

Here, $\mu < 1 - \sigma$ and $\mu^* < 1 - \sigma$ should hold for ν and ν^* to be strictly positive, which holds in this model's calibration. Since we know ν and ν^* , Ω and Ω^* can also be calculated. Then US banks' marginal values ν_H , ν_X , and ν_N are derived from (F.17)-(F.19). Also, ν_F^* , ν_H^* , ν_X^* , and ν_N^* follow directly from (F.27)-(F.30).

Finally, we calibrate the financial friction parameters. Quadratic parameters θ_{H2} , θ_{X2} , θ_{F2}^* , θ_{H2}^* , and θ_{X2}^* are introduced to guarantee stationarity of this model. These parameters are set as 0.005 following [Devereux, Engel, and Wu \(2023\)](#). Then, θ_{H1} , θ_{X1} , θ_{F1}^* , θ_{H1}^* , and θ_{X1}^* are calibrated as

$$\begin{aligned}\theta_{H1} &= \frac{\nu_H}{\mu} - \theta_{H2}qK_H \\ \theta_{X1} &= \frac{\nu_X}{\mu} - \theta_{X2}x \\ \theta_{F1}^* &= \frac{\nu_F^*}{\mu^*} - \theta_{F2}^*q^*K_F^* \\ \theta_{H1}^* &= \frac{\nu_H^*}{\mu^*} - \theta_{H2}^*(1 - x^*)\mathcal{E}qK_H^* \\ \theta_{X1}^* &= \frac{\nu_X^*}{\mu^*} - \theta_{X2}^*x^*\mathcal{E}qK_H^*\end{aligned}$$

Appendix G Impulse Responses

In this section, impulse responses of all variables are presented.

Figure G.1: Impulse Responses to Contractionary US Monetary Policy Shock

(m) Non-US Output

(n) US Investment

(o) Non-US Investment

(p) US Consumption

(q) Non-US Consumption

(r) US Inflation

(s) Non-US Inflation

(t) USD Appreciation Rate

(u) Real Spot Exchange Rate

(v) Real Forward Exchange Rate

(w) Forward premium

Figure G.1: Impulse Responses to Contractionary US Monetary Policy Shock (Continued)

Note. This figure shows impulse responses to 1pp contractionary US monetary policy shock. Time periods of the impulse responses are in quarterly frequency. In each panel, red solid line is the baseline impulse response where US banks are subject to the limit on CIP arbitrage. Impulse responses from the counterfactual economy without the limit on CIP arbitrage are displayed in black dotted lines.

Appendix H Alternative Currency Pricing Paradigm

In this section, we look at implications of alternative currency pricing paradigm other than the local currency pricing. All things except the currency in which prices chosen by firms are denominated and sticky are assumed to be the same as the baseline model. Thus, things that are not mentioned here are maintained as the baseline model.

H.1 Producer Currency Pricing

By the assumption of producer currency pricing (PCP), US wholesalers purchase $Y_{H,t}(j)$ and $Y_{H,t}^*(j)$ at the price of $P_{H,t}(j)$ denominated in USD from US firms, and sell to retailers at $P_{H,t}$ and $P_{H,t}^*$ respectively. $P_{H,t}^*$ is denominated in Euro, so the price of exported goods in terms of USD is $P_{H,t}^*/S_t$ for the nominal spot exchange rate S_t . Then, the profit maximization problems of domestic and export wholesalers yield the following demand functions for each variety as

$$Y_{H,t}(j) = \left(\frac{P_{H,t}(j)}{P_{H,t}} \right)^{-\epsilon} Y_{H,t}$$

$$Y_{H,t}^*(j) = \left(\frac{S_t P_{H,t}(j)}{P_{H,t}^*} \right)^{-\epsilon} Y_{H,t}^*$$

where the price indices of domestic and exported goods are

$$P_{H,t} = \left[\int_0^1 P_{H,t}(j)^{1-\epsilon} dj \right]^{\frac{1}{1-\epsilon}}$$

$$P_{H,t}^* = S_t \left[\int_0^1 P_{H,t}(j)^{1-\epsilon} dj \right]^{\frac{1}{1-\epsilon}}$$

This implies that $P_{H,t}^* = S_t P_{H,t}$, *i.e.* the law of one price holds between the domestic price and the export price. Hence, the demand functions for domestic and exported varieties become

$$Y_{H,t}(j) = \left(\frac{P_{H,t}(j)}{P_{H,t}} \right)^{-\epsilon} Y_{H,t} \tag{H.1}$$

$$Y_{H,t}^*(j) = \left(\frac{P_{H,t}(j)}{P_{H,t}} \right)^{-\epsilon} Y_{H,t}^* \tag{H.2}$$

Similarly, non-US wholesalers purchase $Y_{F,t}^*(j)$ and $Y_{F,t}(j)$ at the price of $P_{F,t}^*(j)$ denominated in Euro while they are sold at $P_{F,t}^*$ and $P_{F,t}$ respectively. Then, the demand functions for domestically-

spent and exported varieties become

$$Y_{F,t}^*(j) = \left(\frac{P_{F,t}^*(j)}{P_{F,t}^*} \right)^{-\epsilon} Y_{F,t}^* \quad (\text{H.3})$$

$$Y_{F,t}(j) = \left(\frac{P_{F,t}^*(j)}{P_{F,t}^*} \right)^{-\epsilon} Y_{F,t} \quad (\text{H.4})$$

using the law of one price $P_{F,t}^* = S_t P_{F,t}$.

Both the prices of domestically-sold and exported US goods are denominated and sticky in USD due to the assumption of PCP. Then, US firm j 's periodic profit $\Pi_t^P(j)$ is given by

$$\Pi_t^P(j) = (1+s)P_{H,t}(j)(Y_{H,t}(j) + Y_{H,t}^*(j)) - TC_t(j) - \frac{\psi_P}{2} \left(\frac{P_{H,t}(j)}{P_{H,t-1}(j)} - 1 \right)^2 P_{H,t}(Y_{H,t} + Y_{H,t}^*)$$

From (H.1) and (H.2), we know that

$$Y_{H,t}(j) + Y_{H,t}^*(j) = \left(\frac{P_{H,t}(j)}{P_{H,t}} \right)^{-\epsilon} (Y_{H,t} + Y_{H,t}^*)$$

Hence, we can solve the firm j 's life-time profit maximization problem from the period t

$$\max_{\{P_{H,t+s}(j)\}_{s=0}^{\infty}} E_t \sum_{s=0}^{\infty} \Lambda_{t,t+s} \Pi_{t+s}^P(j)$$

which yields the first-order condition as

$$(1+s)(\epsilon-1) = \epsilon \frac{MC_t}{P_{H,t}} - \psi_P \left(\frac{P_{H,t}}{P_{H,t-1}} - 1 \right) \frac{P_{H,t}}{P_{H,t-1}} + E_t \left[\Lambda_{t,t+1} \psi_P \left(\frac{P_{H,t+1}}{P_{H,t}} - 1 \right) \left(\frac{P_{H,t+1}}{P_{H,t}} \right)^2 \left(\frac{Y_{H,t+1} + Y_{H,t+1}^*}{Y_{H,t} + Y_{H,t}^*} \right) \right] \quad (\text{H.5})$$

By the same way, non-US firm j 's periodic profit $\Pi_t^{P^*}(j)$ is

$$\Pi_t^{P^*}(j) = (1+s^*)P_{F,t}^*(j)(Y_{F,t}^*(j) + Y_{F,t}(j)) - TC_t^*(j) - \frac{\psi_P}{2} \left(\frac{P_{F,t}^*(j)}{P_{F,t-1}^*(j)} - 1 \right)^2 P_{F,t}^*(Y_{F,t}^* + Y_{F,t})$$

where $P_{F,t}^*(j)$ is the Euro-denominated price chosen by the firm. Since (H.3) and (H.4) imply

$$Y_{F,t}^*(j) + Y_{F,t}(j) = \left(\frac{P_{F,t}^*(j)}{P_{F,t}^*} \right)^{-\epsilon} (Y_{F,t}^* + Y_{F,t})$$

firm j 's life-time profit maximization problem defined as

$$\max_{\{P_{F,t+s}^*(j)\}_{s=0}^{\infty}} E_t \sum_{s=0}^{\infty} \Lambda_{t,t+s}^* \Pi_{t+s}^{P^*}(j)$$

yields the following first-order condition:

$$(1 + s^*)(\epsilon - 1) = \epsilon \frac{MC_t^*}{P_{F,t}^*} - \psi_P \left(\frac{P_{F,t}^*}{P_{F,t-1}^*} - 1 \right) \frac{P_{F,t}^*}{P_{F,t-1}^*} + E_t \left[\Lambda_{t,t+1}^* \psi_P \left(\frac{P_{F,t+1}^*}{P_{F,t}^*} - 1 \right) \left(\frac{P_{F,t+1}^*}{P_{F,t}^*} \right)^2 \left(\frac{Y_{F,t+1}^* + Y_{F,t+1}}{Y_{F,t}^* + Y_{F,t}} \right) \right] \quad (\text{H.6})$$

Since the law of one price holds, $T_t = T_t^*$ and $\mathcal{E}_t^H = \mathcal{E}_t^F = 1$. Hence, the real exchange rate $\mathcal{E}_t$ is

$$\mathcal{E}_t = \left[\frac{\omega + (1 - \omega)T_t^{1-\nu}}{\omega T_t^{1-\nu} + 1 - \omega} \right]^{\frac{1}{1-\nu}} \quad (\text{H.7})$$

The resource constraints for $Y_{H,t}$, $Y_{H,t}^*$, $Y_{F,t}^*$, and $Y_{F,t}$ are derived as

$$\left[1 - \frac{\psi_P}{2} \left(\frac{P_{H,t}}{P_{H,t-1}} - 1 \right)^2 \right] Y_{H,t} = \omega \left(\frac{P_{H,t}}{P_t} \right)^{-\nu} \left[C_t + I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1 \right)^2 \right) \right] \quad (\text{H.8})$$

$$\left[1 - \frac{\psi_P}{2} \left(\frac{P_{H,t}}{P_{H,t-1}} - 1 \right)^2 \right] Y_{H,t}^* = (1 - \omega) \left(\frac{P_{H,t}^*}{P_t^*} \right)^{-\nu} \left[C_t^* + I_t^* \left(1 + \frac{\psi_I}{2} \left(\frac{I_t^*}{I_{t-1}^*} - 1 \right)^2 \right) \right] \quad (\text{H.9})$$

$$\left[1 - \frac{\psi_P}{2} \left(\frac{P_{F,t}^*}{P_{F,t-1}^*} - 1 \right)^2 \right] Y_{F,t}^* = \omega \left(\frac{P_{F,t}^*}{P_t^*} \right)^{-\nu} \left[C_t^* + I_t^* \left(1 + \frac{\psi_I}{2} \left(\frac{I_t^*}{I_{t-1}^*} - 1 \right)^2 \right) \right] \quad (\text{H.10})$$

$$\left[1 - \frac{\psi_P}{2} \left(\frac{P_{F,t}}{P_{F,t-1}} - 1 \right)^2 \right] Y_{F,t} = (1 - \omega) \left(\frac{P_{F,t}}{P_t} \right)^{-\nu} \left[C_t + I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1 \right)^2 \right) \right] \quad (\text{H.11})$$

while the balance of payment equation becomes

$$\begin{aligned} & \left(1 - \frac{\psi_P}{2} \left(\frac{P_{H,t}}{P_{H,t-1}} - 1 \right)^2 \right) P_{H,t} Y_t - P_t \left[C_t + I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1 \right)^2 \right) \right] \\ & + \left(R_{t-1}^* \frac{S_{t-1}}{F_{t-1}} - 1 \right) X_{t-1} - (R_{K,t} - 1) Q_{t-1} K_{H,t-1}^* = (X_t - Q_t K_{H,t}^*) - (X_{t-1} - Q_{t-1} K_{H,t-1}^*) \end{aligned} \quad (\text{H.12})$$

Figure H.1 shows impulse responses to 1pp contractionary US monetary policy shock under the PCP paradigm. Red solid line is the impulse responses of the baseline economy while the black dotted line is the impulse responses of the counterfactual economy. Overall, qualitative features

of impulse responses are similar to the ones derived from the LCP paradigm: there still exists the amplification of spillover to the non-US and spillback to the US.

The main difference of the PCP paradigm comes from the law of one price and the following complete exchange rate pass-through to import price denominated in the destination country's currency. As the USD appreciates in response to higher US policy rate, the non-US import price (from the US) denominated in EUR rises while the US import price (from the non-US) denominated in USD drops since prices are sticky in their own currency. This strengthens the decline in US inflation rate while dampening the decline in non-US inflation rate. By the systematic component of monetary policy, US policy rate rises less while non-US policy rate rises more. As a result, US capital and investment decrease less while non-US capital and investment decrease more. However, the widening of CIP deviations is almost the same as the LCP paradigm, implying the similar amplification of spillovers and spillbacks.

Figure H.1: Impulse Responses to Contractionary US Monetary Policy Shock (Continued)

Note. This figure shows impulse responses to 1pp contractionary US monetary policy shock under producer currency pricing. Time periods of the impulse responses are in quarterly frequency. In each panel, red solid line is the baseline impulse response where US banks are subject to the limit on CIP arbitrage. Impulse responses from the counterfactual economy without the limit on CIP arbitrage are displayed in black dotted lines.

H.2 Dominant Currency Pricing

Under dominant currency pricing (DCP), prices are denominated and sticky in the dominant currency, which is assumed to be the USD here. For the US, this is exactly the same as the PCP. Alike the PCP, US wholesalers purchase $Y_{H,t}(j)$ and $Y_{H,t}^*(j)$ at $P_{H,t}(j)$ denominated in USD from US firms. Hence, the law of one price between the domestic price and the export price holds, *i.e.*, $P_{H,t}^* = S_t P_{H,t}$, and the demand functions for domestic and exported varieties are

$$Y_{H,t}(j) = \left(\frac{P_{H,t}(j)}{P_{H,t}} \right)^{-\epsilon} Y_{H,t} \quad (\text{H.13})$$

$$Y_{H,t}^*(j) = \left(\frac{P_{H,t}(j)}{P_{H,t}} \right)^{-\epsilon} Y_{H,t}^* \quad (\text{H.14})$$

Also, $P_{H,t}(j)$ is determined by the following first-order condition:

$$(1+s)(\epsilon-1) = \epsilon \frac{MC_t}{P_{H,t}} - \psi_P \left(\frac{P_{H,t}}{P_{H,t-1}} - 1 \right) \frac{P_{H,t}}{P_{H,t-1}} + E_t \left[\Lambda_{t,t+1} \psi_P \left(\frac{P_{H,t+1}}{P_{H,t}} - 1 \right) \left(\frac{P_{H,t+1}}{P_{H,t}} \right)^2 \left(\frac{Y_{H,t+1} + Y_{H,t+1}^*}{Y_{H,t} + Y_{H,t}^*} \right) \right] \quad (\text{H.15})$$

On the other hand, from the point of view of the non-US, DCP is exactly the same as the LCP. Non-US wholesalers purchase $Y_{F,t}^*(j)$ at $P_{F,t}^*(j)$ denominated in Euro and $Y_{F,t}(j)$ at $P_{F,t}(j)$ denominated in USD since $Y_{F,t}^*(j)$ is sold in domestic market while $Y_{F,t}(j)$ is sold to the US. Then, the demand functions for domestically-spent and exported varieties become

$$Y_{F,t}^*(j) = \left(\frac{P_{F,t}^*(j)}{P_{F,t}^*} \right)^{-\epsilon} Y_{F,t}^* \quad (\text{H.16})$$

$$Y_{F,t}(j) = \left(\frac{P_{F,t}(j)}{P_{F,t}} \right)^{-\epsilon} Y_{F,t} \quad (\text{H.17})$$

Note that the law of one price between $P_{F,t}^*$ and $P_{F,t}$ does not generally hold. Also, $P_{F,t}^*$ and $P_{F,t}$ are

determined by the first-order conditions which are the same as the LCP:

$$(1 + s^*)(\epsilon - 1) = \epsilon \frac{MC_t^*}{P_{F,t}^*} - \psi_P \left(\frac{P_{F,t}^*}{P_{F,t-1}^*} - 1 \right) \frac{P_{F,t}^*}{P_{F,t-1}^*} + E_t \left[\Lambda_{t,t+1}^* \psi_P \left(\frac{P_{F,t+1}^*}{P_{F,t}^*} - 1 \right) \left(\frac{P_{F,t+1}^*}{P_{F,t}^*} \right)^2 \frac{Y_{F,t+1}^*}{Y_{F,t}^*} \right] \quad (\text{H.18})$$

$$(1 + s^*)(\epsilon - 1) = \epsilon \frac{MC_t^*}{S_t P_{F,t}^*} - \psi_P \left(\frac{P_{F,t}^*}{P_{F,t-1}^*} - 1 \right) \frac{P_{F,t}^*}{P_{F,t-1}^*} + E_t \left[\Lambda_{t,t+1}^* \psi_P \left(\frac{P_{F,t+1}^*}{P_{F,t}^*} - 1 \right) \left(\frac{P_{F,t+1}^*}{P_{F,t}^*} \right)^2 \frac{S_{t+1}}{S_t} \frac{Y_{F,t+1}^*}{Y_{F,t}^*} \right] \quad (\text{H.19})$$

The resource constraints for $Y_{H,t}$, $Y_{H,t}^*$, $Y_{F,t}^*$, and $Y_{F,t}$ are

$$\left[1 - \frac{\psi_P}{2} \left(\frac{P_{H,t}}{P_{H,t-1}} - 1 \right)^2 \right] Y_{H,t} = \omega \left(\frac{P_{H,t}}{P_t} \right)^{-\nu} \left[C_t + I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1 \right)^2 \right) \right] \quad (\text{H.20})$$

$$\left[1 - \frac{\psi_P}{2} \left(\frac{P_{H,t}}{P_{H,t-1}} - 1 \right)^2 \right] Y_{H,t}^* = (1 - \omega) \left(\frac{P_{H,t}^*}{P_t^*} \right)^{-\nu} \left[C_t^* + I_t^* \left(1 + \frac{\psi_I}{2} \left(\frac{I_t^*}{I_{t-1}^*} - 1 \right)^2 \right) \right] \quad (\text{H.21})$$

$$\left[1 - \frac{\psi_P}{2} \left(\frac{P_{F,t}^*}{P_{F,t-1}^*} - 1 \right)^2 \right] Y_{F,t}^* = \omega \left(\frac{P_{F,t}^*}{P_t^*} \right)^{-\nu} \left[C_t^* + I_t^* \left(1 + \frac{\psi_I}{2} \left(\frac{I_t^*}{I_{t-1}^*} - 1 \right)^2 \right) \right] \quad (\text{H.22})$$

$$\left[1 - \frac{\psi_P}{2} \left(\frac{P_{F,t}}{P_{F,t-1}} - 1 \right)^2 \right] Y_{F,t} = (1 - \omega) \left(\frac{P_{F,t}}{P_t} \right)^{-\nu} \left[C_t + I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1 \right)^2 \right) \right] \quad (\text{H.23})$$

while the balance of payment equation is

$$\begin{aligned} & \left(1 - \frac{\psi_P}{2} \left(\frac{P_{H,t}}{P_{H,t-1}} - 1 \right)^2 \right) P_{H,t} Y_t - P_t \left[C_t + I_t \left(1 + \frac{\psi_I}{2} \left(\frac{I_t}{I_{t-1}} - 1 \right)^2 \right) \right] \\ & + \left(R_{t-1}^* \frac{S_{t-1}}{F_{t-1}} - 1 \right) X_{t-1} - (R_{K,t} - 1) Q_{t-1} K_{H,t-1}^* = (X_t - Q_t K_{H,t}^*) - (X_{t-1} - Q_{t-1} K_{H,t-1}^*) \end{aligned} \quad (\text{H.24})$$

In Figure H.2, we can see impulse responses of the baseline and the counterfactual economy under DCP. As the PCP paradigm, DCP shows qualitatively similar amplification of spillover and spillback in response to the contractionary US monetary policy shock. Also, since the DCP is in the middle of the PCP and the LCP, impulse responses are also in the middle of the two pricing paradigms. The difference in impulse responses also comes from whether the law of one price holds or not: it holds for US-produced goods but not for non-US-produced goods. The appreciation of the USD leads to the increase in the non-US import price (from the US) denominated in EUR, dampening the decline in non-US inflation rate. Although the US import price (from the non-US) denominated

in USD is not directly affected, non-US' lower demand for US goods shrinks US aggregate demand and leads to lower US inflation rate. Accordingly, US policy rate rises less than the LCP but more than the PCP while non-US policy rate rises more than the LCP but less than the PCP. Again, the widening of CIP deviations is similar to the case of LCP or PCP.

Impulse responses from the counterfactual economy without the limit on CIP arbitrage are displayed in black dotted lines.

Appendix I Sensitivity Analysis

In this section, we look at whether the choice of quadratic parameters for leverage constraint θ_{H2} , θ_{X2} , θ_{F2}^* , θ_{H2}^* , and θ_{X2}^* affect the results of this model or not. For a computational reason, I change values of θ_{X2} fixing other parameters at 0.005 since the friction in the FX swap market is the main ingredient of this paper. In detail, I choose 100 number of $\theta_{X2} \in (0.001, \theta_{X1}/\bar{x})$. The end point is set at $\theta_{X1}/\bar{x}$ to guarantee positive leverage constraints since the leverage constraint on FX swap is $\theta_{X1} + \theta_{X2}(x_t - \bar{x}) = (\theta_{X1} - \theta_{X2}\bar{x}) + \theta_{X2}x_t$. Then, impulse responses are obtained from the model with each value of θ_{X2} . If the baseline model is robust to the choice of θ_{X2} , then the impulse responses from choices of θ_{X2} should not vary substantially.

Figure [I.1](#) shows the impulse responses to 1pp contractionary US monetary policy shock. Blue solid line with dots is the baseline impulse response where $\theta_{X2} = 0.005$ while impulse responses from other choices of θ_{X2} is displayed as skyblue lines. We can see that impulse responses are not mostly affected by, and thus robust to, the choice of θ_{X2} .
